
2.0 METHODOLOGY

To the extent possible, identification parameters (e.g., proponent/project name and/or location) and impact-causing parameters were identified for each of the past and present and RFD actions identified in this report. These parameters include factors that are common to all resources and resource-specific factors, as discussed below. This information was used to describe the past and present actions and RFD scenarios analyzed in this study and is summarized in **Tables A-1** through **A-8** in Appendix A. These summaries have been formatted to facilitate the Task 3 impact analyses.

The end of year 2003 existing disturbance acreages for this study were based on the database compiled for this Task 2 report (**Tables A-2** through **A-5** and **Tables A-7** and **A-8**) and, where resource-specific data were required, the associated Geographical Information System (GIS) information (**Tables A-1** and **A-6**). The existing disturbance acreages generated through GIS vary from the disturbance acreages in the Task 2 database due to the following variables. The information in the database was compiled based on information obtained from the data sources and the applied assumptions identified in this Task 2 report. As a result, the database specifies a discrete disturbance acreage for each of the development activities (e.g., coal mines, individual oil and gas wells, etc.) identified for the study. Conversely, the GIS analysis accounted for the spatial relationship of the various development activities, thereby avoiding double counting of disturbance acreages where mapped disturbance areas overlap. In addition, the application of the new-versus-existing well disturbance acreage assumptions varied, as follows. For the database, the number of new wells developed during 2003 versus the number of existing wells at the end of 2003 was quantified, and the appropriate acreage assumptions were applied. The observed ratio in the database between new and existing wells could be determined at the subwatershed level; however, the breakdown could not be applied to the resource-specific information within each subwatershed due to the lack of actual discrete locations for new versus existing wells in the GIS map layers. As a result, for GIS calculation purposes, the existing well acreage was applied to all (existing and new) wells in the GIS layer. Also, slight variations between the GIS study area boundary and GIS resource-specific layers resulted in some under counting of disturbance acreages. Where disturbance acreages are presented in this study, the appropriate source is noted.

Future disturbance and reclamation acreages for the RFD scenarios in this study were based on the database compiled for this report due to the following variables and uncertainties associated with using GIS analysis for defining this information. The methodology and assumptions in Appendix B relative to oil and gas development provide a means of identifying the number of new wells to be developed and the number of existing wells to be plugged and abandoned within each of the subwatersheds for each of the target years for this study (i.e., 2010, 2015, and 2020). However, discrete locations for new and plugged and abandoned well sites for these future time periods are not available. For coal mines, the methodology and assumptions presented in Section 3.1 provide for calculation of future disturbance and reclamation acreages. However, although the general area of potential future coal mine-related disturbance can be identified based on projected reserves, the actual disturbance footprint associated with future mining and the actual locations of future reclaimed areas for the target years are not known. As a result, based on existing information, the spatial relationship between projected future disturbance and reclamation areas and the resource-specific information in the GIS layers for these industries cannot be determined. Conversely, the database information does provide for quantification of future disturbance and

2.0 Methodology

reclamation acreages on a subwatershed basis and, with other information (e.g., projected locations of future coal reserves), a means of qualitatively analyzing future resource-specific impacts for those resources that are site-specific (e.g., vegetation, soils, wildlife habitat). The disturbance acreages for the RFD scenarios (based on the Task 2 database) are presented in **Tables A-7** and **A-8** in Appendix A.

2.1 Factors Common to All Resources

Proponent/Project Name. The proponent or operator and associated project name have been identified for tracking purposes in the database for all past, present, and RFD actions with the exception of oil and natural gas (conventional and CBNG) projects and facilities; the latter typically are geographically dispersed and therefore are more appropriately tracked on a general location basis.

Location. Based on the inclusion of project-specific locations in the database, and the structuring of the database using fourth level watersheds (subwatersheds) as a common denominator, the impact-causing parameters within specified areas have been summarized to facilitate cumulative impact evaluations. Mapped locations of the past and present and RFD projects analyzed in this study are presented in Chapter 3.0 in association with the industry-specific discussions.

Timeframe. The database has been structured to link specific, identified levels of development with the target dates for this study. Past and present actions have been summarized based on 2003 (or earlier) data, depending on data availability; parameters for RFD scenarios have been established for 2010, 2015, and 2020 based on information available through the end of 2004.

Land Ownership. Surface ownership in the Wyoming PRB study area is primarily private, with federal and state lands comprising approximately 14 and 8 percent of the area, respectively (see **Figure 1-3**). In the Montana PRB study area, the majority of the land is privately owned, with federal and state lands comprising approximately 25 and 5 percent, respectively. This information has been included in the database to distinguish BLM authorizing actions from other jurisdictional oversight.

Acreage. Mining activity has been projected forward in 5-year increments based on available reserves and high and low projected production levels to facilitate the estimation of future coal mine disturbance and reclamation. The projected mining activity was combined with industry input from the PRB coal producers, and public historical and permitted reclamation activity data, to forecast future disturbance and reclamation acreages.

Future disturbance and reclamation acreages related to coal technology projects and coal railroad transportation infrastructure were estimated from numerous information sources including: the Dakota, Minnesota, & Eastern Railroad (DM&E) Final Environmental Impact Statement (EIS); Tongue River Railroad U.S. Surface Transportation Board (STB) application; Montgomery Watson Harza (MWH) Coal Planning Report; Burlington Northern and Santa Fe Railroad (BNSF) Guide to Coal Mines report; Wyoming Department of Environmental Quality (WDEQ), Land Quality Division (LQD) annual reports for individual mines; Montana Department of Environmental Quality (MDEQ) mine permit documents; and related trade magazine articles. Information compiled from these sources was compared against historical production levels. Future disturbance and reclamation

acreages were projected to correspond to historical trends for the high and low production forecasts.

Acreages for other past and present and RFD actions were obtained from permit applications, EISs or environmental assessments (EAs), or estimated, where appropriate, based on typical facility sizes (e.g., well pads).

Schedule. The estimated schedule for the construction, operation, and closure/reclamation of proposed coal mines, non-coal mines, coal technology projects, and coal railroad transportation infrastructure, was derived from public information on record with the WDEQ and MDEQ, industry input, and detailed mine-specific reserve sequencing projections. Given the projected high and low production rates, there are adequate economic reserves to sustain all proposed coal mining activity through the year 2020.

Schedules for other past and present and RFD actions have been based on industry input, permitting documents, and assumptions related to trends for interrelated industries (e.g., coal production forecasts in relation to rail capacity).

Production Estimate. Analysis of historic PRB coal production levels, and current reports forecasting future PRB coal market activity from sources including Hill and Associates, Inc., Platts Research and Consulting, Global Insight, and the U.S. Department of Energy (USDOE), were combined with input from the PRB coal mine operators, and regulatory agency input from specialists within the Wyoming and Montana BLM, WDEQ, and MDEQ to project the upper and lower total coal production levels for the PRB. Individual mine production then was allocated based on historic market share performance, current air quality permit limitations, proposed expansion applications on file with the U.S. Environmental Protection Agency (USEPA), WDEQ and MDEQ Air Quality Divisions (AQDs), coal rail loadout capacities, and coal mine operator input.

Capital Investment. Capital investment information relative to RFD actions is presented in the text portion of this report and discussed further in the Task 3C report. Capital investment related to coal mine development was estimated based on requirements for site-specific mine infrastructure (e.g., rail loop and loadout facilities, major mobile equipment purchases, and highway relocations within permitted mine boundaries). Estimated costs are based on historic costs for similar facilities and equipment.

Likelihood. Following identification of the RFDs through year 2020 for the study area, each capital project was assigned a rating for the likelihood of development or occurrence. Both private and public sector activities have been considered. Likelihood ratings were assigned to the identified actions based on the numerical rating system presented below. The numerical rating for each action is identified in the Chapter 3 discussion.

- Certain/highly likely (1) – Inclusive of actions that have been fully funded, permitted, are under construction, or are necessitated to achieve expanded coal output. These actions have an identified proponent/sponsor, project location, and specific details regarding capacity, output, and/or costs.
- Moderately likely (2) – Inclusive of actions for which applications have been submitted to an agency, that are part of a defined capital improvement plan/program, involve an established

2.0 Methodology

technology or process, have an identified proponent/sponsor with a demonstrated track record in undertaking/completing similar or related projects, or for which an EIS or EA is in preparation.

- Low likelihood (3) – Inclusive of actions that are undergoing market or feasibility analyses, previously were proposed but failed to proceed and are now under reconsideration, or for which some descriptive information is available but for which no formal regulatory or administrative approval processes have been initiated.
- Currently unknown - Projects for which insufficient information is available for analysis purposes, or to determine the likelihood of the project moving forward, have been assigned a likelihood of currently unknown. These projects have not been included in the RFD database. Alternately, these actions are identified in text with an explanation for their elimination from consideration.

As oil and gas activities differ from individual capital projects due to the dispersed nature of the facilities, the projection of oil and gas activities reflects their likelihood and timeframe.

2.2 Resource-specific Factors

Air Emissions Estimates. Information relative to current conditions has been based on air emissions inventories obtained from WDEQ, MDEQ, and the modeling input files from the Final Environmental Impact Statement and Proposed Plan Amendment for the Powder River Basin Oil and Gas Project (BLM 2003a), as obtained from Argonne National Laboratories. Air emissions for RFDs have been based on average operations in 2002 and earlier. For each group of sources, an average emissions profile was developed for modeling purposes, based on production and design data.

Water Production/Disposal. Coal mine-related groundwater production data were obtained from individual mine operators and data as reported to the Wyoming State Engineer's Office for permitted wells through 2002. This data and the assumptions presented in Section 3.1.4 of this report were used to determine the future coal mine-related groundwater pumping rates.

Current and future water production and disposal volumes associated with conventional oil and gas and CBNG development have been based on data in the IHS Energy Services™ (IHS) (2004) and Wyoming Oil and Gas Conservation Commission (WOGCC) (2004) databases.

Water Consumption. Dust suppression practices at active coal mines are the single largest factor in water consumption, accounting for an estimated 85 percent of the total water used. Mine operators are required to submit an annual fugitive emissions control report to the WDEQ/AQD that summarizes the annual gallons of water consumed, dust suppression additives, and application techniques used to control dust emissions. For coal mines in the Wyoming PRB, the past several years of reports were reviewed and analyzed, and future water consumption was projected forward based on current practices and forecasted production levels. Water consumption projections for Montana mines were based on the information for Wyoming mines and adjusted for annual production and mining method.

Current and future non-coal mine, coal technology projects, and coal railroad transportation-related water consumption is expected to be minimal and was estimated from existing data on file with the

WDEQ and MDEQ, as applicable. Power plant-related water consumption was estimated based on recent analyses at other facilities.

Workforce. Current and future PRB coal mine-related Wyoming employment was estimated by reviewing the past seven annual reports of the Wyoming State Mine Inspector, correlating productivity gains to changes in mine production, and forecasting total employment forward as a function of mine productivity and production. Montana employment information was based on historic levels of personnel from U.S. Mine Safety and Health Administration (MSHA) records.

Current and future non-coal mine, coal technology projects, and coal railroad transportation-related employment is expected to be minimal and was estimated from existing data on file with the WDEQ and MDEQ, as applicable.

Current and future Wyoming workforce requirements for the oil and gas industry are a function of the pace of drilling, number of producing wells, anticipated production life of the wells, and future reclamation activities. Employment assumptions for modeling of social and economic impacts are discussed in the Task 3C report.

Current and future Wyoming workforce requirements for power plants in the PRB are based on information obtained from the operators, project application filings, local economic development organizations, and the Wyoming Department of Employment.
