ENVIRONMENTAL ASSESSMENT
LIVESTOCK GRAZING AUTHORIZATION

EA Number        CA 170-02-66

Allotment Number and Name(s)

  6021  Shannon Canyon/Baker Creek
  6023  Black Mine
  6042  Ash Creek
  6046  Alabama Hills
  6047  Red Mountain
  6049  Aberdeen
  6050  Poverty Hills
  6079  East Crater Mountain
  6080  Blind Springs
  6082  George Creek

BL M Bishop Field Office
    Prepared
    February 2003
CHAPTER 1: INTRODUCTION

The Bureau of Land Management (BLM) is proposing to issue a 10 year long grazing permit on these allotments to authorize livestock grazing. The approximate allotments Public Land acreages are:

<table>
<thead>
<tr>
<th>Allotment Name</th>
<th>Public Land acres</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shannon Canyon/Baker Creek</td>
<td>3,000</td>
</tr>
<tr>
<td>Black Mine</td>
<td>1,658</td>
</tr>
<tr>

</tr>
<tr>
<td>Blind Springs</td>
<td>5,870</td>
</tr>
<tr>
<td>George Creek</td>
<td>6,082</td>
</tr>
</tbody>
</table>

The allotments are located in the Owens Lake, Owens Valley, and Benton Management Area of the Bishop Field Office. Their elevation range is between 3,700 and 6,800 feet. Vegetation communities are a mix of Great Basin Big Sagebrush and Bitterbrush, Great Basin Saltbush Scrub, Shadscale Scrub, and other mixed desert shrubs.

Need for the Proposed Action

The proposed action is needed to authorize grazing in accordance with grazing regulation 43 CFR 4100 and be consistent with the provisions of the Taylor Grazing Act, Public Rangelands Improvement Act, and Federal Land Policy and Management Act. Action may be required to maintain or improve resource conditions including rangeland health. Status of existing permit/lease: The grazing permits for these allotments will expire on 2/28/03. In accordance with the National Environmental Policy Act (NEPA), an Environmental Assessment (EA) must be prepared to analyze the affects of livestock grazing, in order to determine if re-authorizing the grazing permit(s) is appropriate.

Plan Conformance: The proposed action is subject to the following plan:

The proposed action has been determined to be in conformance with this plan as required by regulation (43 CFR §1610.5-3(a)).

Remarks: The proposed action will occur in an area identified for livestock grazing in the Bishop Resource Management Plan. The proposed action is consistent with the land use decisions and
resource management goals and objectives of the plan, pages 8 thru 23 and 40 thru 46.

The ten allotments meet all of the Secretary of Interior’s Approved Rangeland Health Standards as indicated in the BLM California Rangeland Health Environmental Impact Statement and Decisions Record of July 2000.

Rangeland Health field assessments of the Standards were completed on these dates:

<table>

</tbody>
</table>

A database detailing the results of these assessments has been completed and is located in the resources/images/range computer directory at the BLM Bishop Field Office.

**Relationship to Statutes, Regulations, and Plans**

**Endangered Species**

Several of the allotments are within the range of federally listed threatened or endangered species. However, no Endangered Species are present or likely to occur, based on historical records, field monitoring, and/or habitat suitability in these allotments. Pursuant to Section 7 of the Endangered Species Act, formal consultation with the Fish and Wildlife Service (FWS) is required on all allotments for which livestock grazing may affect listed species. The stipulations of any grazing permit may be modified to conform to the terms and conditions specified in a FWS biological opinion to minimize take of listed animal species. In addition, the terms and conditions of any grazing permit may also be modified to conform to decisions made to achieve recovery plan objectives as determined through subsequent land use plan amendments or revisions. All Section 7 consultations with FWS were completed in 2000.

**Special Status Plant Species**

Special Status Plant Species are those species that have been listed by the California Native Plant Society as List 1B species, which includes plants that are rare, threatened or endangered in California and elsewhere. All of the plants constituting List 1B meet the definition of Sec. 1901, Chapter 10 (Native Plant Protection Act) or Secs. 2062 and 2067 (California Endangered Species Act) of the California Department of Fish and Game Code, and are eligible for state listing. The Bishop Resource Management Plan (RMP, 1993, p. 17) stipulates yearlong protection of
sensitive plants (Special Status Plants) and their associated habitats.

The following allotments contain or are in the vicinity of this CNPS List 1B species:

<table>
<thead>
<tr>
<th>Allotment</th>
<th>Plant Species</th>
<th>Population Trend</th>

</tr>
<tr>
<td>Poverty Hills</td>
<td>Sagebrush loeflingia ((Loeflingia squarrosa var. artemisiarum))</td>
<td>Annual species - Unknown</td>
</tr>
</tbody>
</table>

Grazing impacts to these populations have been minimized by avoidance of these sites during key reproductive periods, e.g. late June-July. The majority of these populations occur on adjoining Los Angeles Department of Water and Power lands. The populations on BLM are isolated and are not currently being impacted by cattle grazing. In addition, trend within these populations is tied primarily to climatic fluctuations; however annual species trend is likely also impacted by annual red brome invasions that are a result of historic grazing.

Cultural Resources

California BLM has the responsibility to manage cultural resources on public lands pursuant to the 1966 National Historic Preservation Act, the 1980 Rangeland Programmatic Memorandum of Agreement with the Advisory Council on Historic Places (WO IM 80-369), the 1997 Programmatic Agreement Among the Bureau of Land Management, the Advisory Council on Historic Preservation, and the National Conference of State Historic Preservation Officers Regarding the Manner in Which BLM Will Meet Its Responsibilities Under the National Historic Preservation Act, the State Protocol Agreement Between the California State Director of the Bureau of Land Management and the California State Historic Preservation Officer (1998) and other internal policies.

The stipulations of any grazing permit may be modified to reflect the presence of cultural resources. Background site record and literature review will be conducted as a minimum level of review as part of the permit renewal EA. Present inventory will focus on known or suspected
areas of historic ground disturbing activities associated with livestock grazing such as water sources, corrals, supplemental feeding areas, bedding areas, salt block stations. In general, following the Bishop Field Office research design for grazing assessments (Halford 1999), all areas with a high probability for the congregation of cattle and for the occurrence of significant cultural resources will be field evaluated. The results of these analyses will be used to modify grazing permits to protect or mitigate impacts to cultural resources.

Wilderness and Wild and Scenic Rivers

These allotments do not occur within any designated Wilderness Area. However, the allotments contain several Wilderness Study Areas. These include CA-010-057 (Independence Creek WSA), CA-010-062 (Crater Mountain WSA), CA-010-064 (Symmes Creek) and CA-010-079 (Chidago Canyon WSA). Virtually all of the Symmes Creek and Independence Creek WSAs are within the allotments while only about half of the Crater Mountain and Chidago Canyon WSAs are within the allotments designated in this environmental assessment.

Wilderness values are described in the 1979 Final Wilderness Intensive Inventory Report while the WSA’s existing range and other improvements are identified in the 1990 California Statewide Wilderness Study Report (WSR). The Interim Management Policy for Lands Under Wilderness Review (IMP) provides direction for grazing management in WSAs until the WSA is designated wilderness or released from the wilderness review process. Continued livestock grazing within this allotment would be in compliance with the BLM Wilderness Interim Management Policy (IMP) (Appendix A.).

The allotments contain no designated Wild and Scenic Rivers. However, the allotments do contain approximately six miles of creeks determined to be eligible for wild and scenic rivers study within the Bishop RMP (1993). These creeks include Independence and George Creeks. Both creeks are classified as recreational.

Wild and scenic river values are described in Appendix 2 of the draft Bishop RMP and EIS dated September of 1990. The Interim Management Guidelines for Study Rivers provides direction for grazing management on eligible creeks until the creek is designated a wild and scenic river or released from the wild and scenic river review process. Continued livestock grazing within this allotment would be in compliance with this policy. For further information, see Appendix 3 of the final Bishop RMP and EIS dated August of 1991.

Water Quality

Direction for implementation of the Federal Clean Water Act (CWA) of 1972 (P.L. 92-500, as amended) is provided by the Code of Federal Regulations (40 CFR) and by a variety of USEPA guidance documents on specific subjects. To meet the requirements of the CWA on public lands, BLM is currently developing a state-wide water quality management plan under an MOU with the California Water Resources Control Board. As part of the water quality plan, BLM is required to submit a listing of Best Management Practices (BMPs) to the state and to the U.S. Environmental Protection Agency for approval. Pursuant to the decisions affecting water quality
in the Bishop Resource Management Plan, BMPs for the Field Office area have been submitted to meet the requirements under the CWA.

Section 4180.1 of the Grazing Administration Regulations (4180.1, Federal Register Vol 60, No. 35, pg.9970) directs that certain conditions of rangeland health exist on public lands which include the statement that “water quality complies with State water quality standards and achieves, or is making significant progress toward achieving, established BLM management objectives....” The Standards and Guidelines for Rangeland Health in the Central California area, as it applies to surface and groundwater resources and their quality have as a primary objective to maintain the existing quality and beneficial uses of water, protect them where they are threatened (and livestock grazing activities are a contributing factor), and restore them where they are currently degraded (and livestock grazing activities are a contributing factor). In the following instances the objective becomes a higher priority:

(a) where beneficial uses of water bodies have been listed as threatened or impaired pursuant to Section 303(d) of the CWA;

(b) where aquatic habitat is present or has been present for Federal threatened or endangered, candidate and other special status species dependent on water resources; and

(c) in designated water resource sensitive areas such as riparian and wetland areas.

Air Quality

The Benton Management Area does not lie within a Federal Air Quality Non-Attainment/Maintenance Area. The Benton Management Area is located north of the Owens Valley Management Area (Figure 1).

The Owens Lake Management Area and the southern portion of the Owens Valley Management Area, south of Tinemaha Reservoir, falls within a Federal Air Quality Non-Attainment/Maintenance Area and is subject to the following legal requirement:

Section 176 (c) of the Clean Air Act (CAA), as amended (42 U.S.C. 7401 et seq.) and regulations under 40 CFR part 93 subpart W, with respect to the conformity of general Federal actions to the applicable state implementation plan (SIP) apply to projects within non-attainment areas. Under those authorities, "no department, agency or instrumentality of the Federal Government shall engage in, support in any way or provide financial assistance for, license or permit, or approve any activity which does not conform to an applicable implementation plan". Under CAA 176 (c) and 40 CFR part 93 subpart W, a Federal agency must make a determination that a Federal action conforms to the applicable implementation plan before the action is taken.

( c ) The requirements of this subpart shall not apply to the following Federal actions:

( iii ) Continuing and recurring activities such as permit renewals where activities will be similar in scope and operation to activities currently being conducted.

The Great Basin Unified Air Pollution Control District (GBUAPCD) has state air quality jurisdiction over the Owens Valley Management Area.

CHAPTER 2: PROPOSED ACTION AND ALTERNATIVES

Proposed Action

The proposed action is to continue present management, but with revised Terms and Conditions to the expiring Grazing Permit. The completed Rangeland Health allotment assessments document that continuation of livestock grazing, in the same manner and degree, complies with the intent of the Rangeland Health initiative and its Standards.

Terms and Conditions will be incorporated into the reissued Grazing Permits to ensure compliance with the Rangeland Health Standards and Guidelines and Bishop RMP decisions pertinent to livestock grazing.

B. Range Improvements
There are no existing, nor any proposed new improvements, that need to be eliminated or constructed in order to maintain or achieve rangeland health.

C. Measures to Maintain or Achieve Standards (Revised Terms and Conditions of the Grazing Permit).

1. Grazing use is not to exceed 40% of annual growth on key forage species (all allotments) and leave a 4-6" stubble height on riparian vegetation.
2. No salt or other nutrient supplement placement or sheep bedding within 1/4 mile of creeks, aspen groves, meadows, sage grouse strutting grounds, or special status plant habitat.

3. No supplemental feeding (actual forage, i.e. hay) on public land or private land that is unfenced from the public land at any time.

4. No trailing through a neighboring allotment without the BLM’s authorization.

5. Grazing permits shall contain terms and conditions appropriate to achieve management and resource condition objectives for the public land, or to assist in the orderly administration of the public rangelands and to ensure conformance with the provisions of Subpart 4180 (Fundamentals of Rangeland Health and Standards and Guidelines for Grazing Administration). This is per Subpart 4130.3 Terms & Conditions and Subpart 4130.3-2 Other Terms and Conditions.

6. The authorized officer may modify terms and conditions of the permit when the active use or related management practices are not meeting the land use plan, allotment management plan or other activity plan, or management objectives, or is not in conformance with the provisions of 4180 (Fundamentals of Rangeland Health and Standards & Guidelines for Grazing Administration). This is per Subpart 4130.3-3 Modification of permits or leases.

D. Monitoring

Monitoring would consist of documenting utilization levels to ensure that grazing use does not exceed the 40% level. This would be done annually to assure compliance with terms and conditions of the permit. No long term monitoring methods to determine condition and trend are planned. At some future date, a reassessment of rangeland health may be done using the existing methodology as comparison to current conditions.

No Grazing Alternative

This alternative would result in not reissuing a grazing permit for these allotments. As a result, grazing would be eliminated. This would be a permanent cancellation. The BLM would be required to complete an RMP Plan Amendment process in accordance with BLM Planning Regulations.

CHAPTER 3: ENVIRONMENTAL ANALYSIS

The 18 individual resource templates below combine, by resource, the affected environment, environmental consequences, and consultation sections of required elements of the EA. They include the standard critical elements of the human environment (appendix 5, BLM NEPA
Handbook, as amended) and several other resource elements commonly affected by livestock grazing.

**Required Elements:**

1. Air Quality
2. Areas of Critical Environmental Concern (ACEC)
3. Cultural Resources
4. Environmental Justice
5. Farmlands, Prime or Unique
   
   The proposed action and no grazing alternatives would have no affect on Farmlands because none are present on any of the ten allotments.
6. Flood plains
   
   The proposed action and no grazing alternatives would have no affect on flood plains because there are none on the public lands on any of the ten allotments.
7. Invasive, Non-native Species
8. Native American Concerns
   
   The Native American Tribal Councils, for the seven tribes that reside within the Bishop Field Office jurisdiction, have been contacted and have not expressed any specific concerns relative to the affects of livestock grazing for these ten allotments. There are general concerns that are addressed below.
9. Recreation
   
   The proposed action and no action alternative would have no affect on recreation because of the lack of proposed facilities or management practices that could potentially alter existing recreation uses or use patterns.
10. Social and Economic
11. Soil
12. Waste, Hazardous or Solid
   
   The proposed action and no grazing alternatives would have no affect on Hazardous or
Solid Waste as there are no sites occurring on these ten allotments.

13. Water Quality, Surface and Ground

14. Wetlands/Riparian Zones

15. Wild and Scenic Rivers

There are no designated Wild and Scenic Rivers within these ten allotments. However, proposed grazing within the creeks determined to be eligible for wild and scenic river study mentioned above in Relationship to Statutes, Regulations, and Plans would not impair wild and scenic river values. Riparian and stream values would remain unaffected. If ecological improvements in plant and wildlife habitat occur, then these values would be enhanced. For additional information regarding special features such as cultural values, wildlife, plants, etc., refer to the specific narrative addressing these values in other parts of this document. In conclusion, proposed grazing within allotments would conform with the BLM Wilderness Interim Management Policy for Study Rivers.

16. Wilderness

These allotments do not occur within any designated wilderness area. However, proposed grazing within the Wilderness Study Areas mentioned above in Relationship to Statutes, Regulations, and Plans would not impair wilderness qualities. Wilderness values of naturalness, outstanding opportunities for solitude, and a primitive or unconfined type of recreation would remain unaffected. If ecological improvements in plant and wildlife habitat occur, then naturalness would be enhanced. For additional information regarding special features such as cultural values, wildlife, plants, etc., refer to the specific narrative addressing these values in other parts of this document. In conclusion, proposed grazing within allotments would conform with the BLM Wilderness Interim Management Policy (IMP).

17. Wildlife

18. Wild Horses and Burros

The proposed action and no grazing alternatives would have no affect on Wild Horses and Burros as there are no populations occurring on these ten allotments.

19. Vegetation
AIR QUALITY

A. Affected Environment

Six allotments occur within a federal non-attainment/maintenance area within the Great Basin Unified Air Pollution Control District’s (GBUAPCD) jurisdictional boundaries. The allotments that occur within a federal non-attainment/maintenance area include Poverty Hills, Aberdeen, Black Mine, Alabama Hills, George Creek, and Ash Creek.

B. Environmental Consequences

1. Impacts of Proposed Action

Fugitive dust emissions could occur due to the soil disturbance as a result from the trampling action of the livestock when soil moisture levels are low. Support vehicle use on the access roads will generate small amounts of PM$_{10}$ emissions throughout the grazing area and could carry soils onto the paved roads which would increase entrainment PM emissions. Ruminant animals emit methane gas which is a precursor emission for ozone. The support vehicles emit various precursor emissions for ozone. Actual emissions amounts from this grazing activity are negligible. No significant offsite impacts are anticipated.

2. Impacts of No Grazing

Same as above.

3. Cumulative Impacts

The proposed action area is within the jurisdiction of the Great Basin Unified Air Pollution Control District.

The expected emission levels are within the levels in the attainment demonstrations in the SIPs and the cumulative NAAQS 24 hour and one year PM$_{10}$ emission standards and the one hour ozone emission standards and are not likely to result in or contribute to accedences of the National Ambient Air Quality Standards. These impacts would be the same for both Alternatives.

C. Consultation  Jim Parker, Great Basin Unified Air Pollution Control District( GBUAPCD)

D. Maps  GBUAPCD map of PM10 non-attainment areas (Figure 1)

E. References  None
AREA OF CRITICAL ENVIRONMENTAL CONCERN (ACEC)

A. Affected Environment

Approximately 3 sections (1,920 acres) of the East Crater Mountain allotment occur within the Crater Mountain ACEC. The ACEC was designated in 1993, encompassing nearly 5,735 acres, in recognition of the unique assemblage of resource values. The goals of the ACEC are to protect scenic values, enhance recreation opportunities, and provide for interpretation of geologic features.

B. Environmental Consequences

1. Impacts of Proposed Action

Cattle, customarily, do not frequent the Crater Mountain ACEC eastern boundary. This is due to the rough volcanic topography and the distance from available water. Rarely is there any problem with the cattle from the East Crater Mountain allotment entering the ACEC. Reissuing of the grazing permit would not create any new impacts.

2. Impacts on No Grazing

This alternative would result in an absolute elimination of the possibility of cattle using the East Crater Mountain allotment.

3. Cumulative Impacts

There would be no cumulative impacts under either alternative.

C. Consultation

Previous consultation with the following agencies, which annually review the implementation and monitoring components of the ACEC plan:

U.S. Fish and Wildlife Service
Los Angeles Department of Water and Power (LADWP)
University of California, Natural Reserve System
California Department of Fish and Game

D. Maps

Special Management Areas – Bishop Resource Management Record of Decisions (Figure 2)

CULTURAL RESOURCES

A. Affected Environment

Located on the western fringe of the Great Basin physiographic province the Owens Valley region, incorporated within the Bishop Field Area, contains the highest archaeological site densities within the Great Basin (Basgall and McGuire 1988; Bettinger 1975, 1982). In 1981 and 1982 the BLM completed two Environmental Impact Statements (EIS) addressing grazing on public lands within the Bishop Field Area; “Proposed Livestock Grazing Management for the Benton-Owens Valley Planning Unit”, 1981 and “Proposed Livestock Grazing Management for the Bodie-Coleville Planning Units”, 1982. In both EIS’s cultural resource reviews are limited to Class I literature searches of existing data. The general conclusion was:

Livestock use impacts on cultural resources include: displacement (vertical and horizontal) and breakage of artifacts, and the mixing of depositional associations through trampling; destruction or enhanced deterioration of structures and features through rubbing; and an acceleration of natural erosional processes. Plants valued by Native American traditionalists could be trampled or consumed by livestock, adversely affecting plant availability at some locations. For purposes of analysis it is assumed that the impacts of livestock use are distributed in proportion to the actual distribution of livestock, with the most intensive impacts occurring at livestock use concentration areas. Cultural Resources located on lands having erosional or other types of watershed deterioration problems attributed to livestock use impacts are assumed to receive high impacts. Cultural resources are non-renewable, and impacts of livestock use on cultural resources are cumulative (Bodie-Coleville EIS 1982:4-92).

Using existing survey data (BLM 1978; Busby et al. 1979; Hall 1980; Kobori et al. 1980), site densities were predicted to range from 9 sites per square mile (m²) in the Benton Planning Unit to 4 sites m² in the Owens Valley Planning Unit, with an average of 9.54 sites/m² in the Bodie/Coleville Planning units.

Previous Research on Grazing Impacts to Cultural Resources

Relatively few studies have been undertaken to address the impacts of domestic livestock grazing to archaeological resources (Archaeological Sites Protection and Preservation Notebook: Technical Notes (ASPPN) I-15, 1990; Osborn et al. 1987; Roney 1977; Thomas D. Burke, personal communication 1998), with more emphasis being placed on the effects of human trampling in site formation processes (see Nielson 1991). Nonetheless, the same conclusions have been drawn from these studies as summed by Nielson (1991).

Intensive trampling modifies the horizontal distribution of artifacts, it obscures patterns existing in their original deposition, and eventually introduces new trends in their spatial arrangement. By producing vertical migration of materials it also
can move artifacts across stratigraphic units, and mix in the same deposits items originating in different occupations. When trodden, artifacts undergo several types of damage, like breakage, micro-chipping and abrasion. The resulting traces sometimes mimic the damage produced by use or by other post-depositional processes and therefore can lead unwittingly to erroneous functional interpretations (Nielson 1991:483-484).

Variables influencing the level of impact at any given site include: 1) soil type (e.g., hard or rocky soil substrates will lead to greater artifact damage and horizontal displacement); 2) soil moisture (e.g., wet soils will lead to greater vertical displacement and stratigraphic mixing); 3) vegetation type/ground cover (depending on site landform specifics, erosion may increase as vegetation cover decreases resulting in significant secondary impacts); and 4) intensity of grazing.

The studies reviewed here are experimental tests of trampling impacts (Archaeological Sites Protection and Preservation Notebook: Technical Notes (ASPPN) I-15, 1990; Nielson 1991; Osborn et al. 1987; Roney 1977). All of the studies found that smaller artifacts (< 2 g [ASPPN 1991]) tend to migrate vertically more readily than larger artifacts thus biasing site interpretation in cases where no subsurface analyses are involved. In a controlled experiment within a portable corral, Roney (1977) found that after 40 hours, in which 78 cows were rotated through the corral, that only (5%) of 60 flaked stone artifacts could be found on the surface. The hard soil substrate was churned to a fine dust to 5 cm, 81% of the artifacts were horizontally displaced up to .75 m and 48% were damaged and broken. Roney (1977) concluded that “...cattle do produce significant physical damage to lithic artifacts.”

Nielson (1991), in his assessment of human trampling, found the same trends with top soil loosening occurring to 1-2 cm on a hard soil substrate with subsoils being compacted. Again smaller items tended to migrate downward, but were less apt to move horizontally than large specimens. Sixty percent of the lithic debitage showed damage ranging from abrasion, microflaking, and breakage. As would be expected, ceramics showed the greatest level of impact with a random distribution of sizes being reduced to a skewed, unimodal distribution dominated by smaller size classes less than 30 cm in diameter. We can predict that cattle impacts would be highly magnified over Nielson’s (1991) results from his studies on human trampling, but would follow the same trends.

In field visits Tom Burke (personal communication 1998), owner and principal investigator of Archaeological Research Services, Inc., has found cattle grazing to have “substantial adverse effect to archaeological site integrity”. In heavy use areas mixing can occur up to 10-20 cm in most conditions and up to 30-40 cm in wet conditions. The author’s field investigations corroborate Burke’s assessments. As would be expected, Burke has found impacts to be highest in areas where cattle tend to congregate such as springs, water courses, troughs, shade zones, and salt licks. The zone of impact around such features extends from 25-100 meters, with a linear pattern of roughly 25 to 50 meters following stream courses. Field assessments in the Bishop Field Area support these observations.
In summary, it can be concluded that livestock grazing can have adverse effects to archaeological resources causing artifact damage, movement, and mixing. In the case of standing structures, cattle rubbing or scratching can cause severe impacts causing structure degradation and collapse (Chuck Fell, Bodie State Historical Park, personal communication 1995). Intensity of grazing, soil hardness, moisture, vegetation cover, and type are factors influencing the level and types of impacts. Erosion is a secondary impact resulting from grazing that can also have negative effects to cultural sites. The areas of greatest concern are those locations where cattle congregate and tend to spend a large percentage of their time. In zones where cattle are more dispersed, such as upland locations, it can be predicted that impacts will be mainly surficial, causing no stratigraphic mixing, but perhaps resulting in horizontal displacement of artifacts. In rocky areas and zones without sufficient feed very little to no cattle impact is expected to occur (field observations 1999).

B. Environmental Consequences

1. Impacts of Proposed Action

Cattle use on the subject allotments is generally highly dispersed. Due to the fact that no known sites occur within areas of heavy congregation, impacts to cultural properties are predicted to be minimal as a result of the proposed action.

2. Impacts of No Grazing

This alternative would eliminate all threats of damage to cultural properties that could result from the proposed action.

3. Cumulative Impacts

Cultural resources would be cumulatively affected from a variety of actions including livestock grazing. Continued trailing through a site may cause horizontal movement of artifacts, including artifact damage and wear. These types of impacts will be, generally, highly localized and would not adversely affect those properties of a given site which may make it eligible for listing on the National Register of Historic Places. Areas of continual cattle congregation and those where wallowing is prevalent can result in significant cumulative impacts to a cultural property, causing both horizontal and vertical mixing of deposits, artifact damage, and negative impacts to features such as living floors, hearths, and house structures. Field evaluations will identify high-use, congregation areas. In those areas where cultural resource values are significant, appropriate mitigation measures will be devised to reduce and abate impacts.

ENVIRONMENTAL JUSTICE

A. Affected Environment

There are no low-income or minority populations living on any of the allotments.

There are seven Native American communities in the Eastern Sierra, which are near allotments. Members of these communities do some hunting and subsistence collecting of materials from public lands on various allotments – pinyon nuts, basket weaving materials, medicinal plants, etc.

There may be some low-income Hispanic or other ethnic minorities working on various allotments, working for some of the cattle and sheep operations. Depending upon actual decisions made, there may be some impacts to certain individuals.

B. Environmental Consequences

1. Impacts of Proposed Action

Continued livestock grazing would have no affect upon any low-income or minority populations. If any changes in grazing operations are required, there may be a loss of a job to a member of a low-income or minority population. There may also be new jobs created. Any such impacts would be limited to a single job here or there and there would not be a disproportionate impact, either negative or positive, to such a group.

2. No Grazing

If there were no grazing allowed on public land, there may be a loss of some jobs to members of a low-income or minority population. Any such impacts would be limited to a single job here or
there and would not be a disproportionate impact to such a group.

There might be a slight positive impact to some groups through increased availability of some resources that are collected on public lands. This would however vary by area and type of resource, and would probably be minimal.

3. **Cumulative Impacts**

Cumulative impacts to low income or minority populations from past, present, and reasonably foreseeable public or private actions including any actions on non federal lands would be extremely low and would not be disproportionate to impacts on other segments of the population under any of the alternatives. A “no grazing” scenario would potentially have the most negative impact, but again, would not be disproportionate to the low income or minority population.

**C. Consultation**

There are seven Native American communities in the Eastern Sierra, which are near allotments.

When we began the allotment assessment process in 1999, these communities were all contacted by letter (January 11, 1999), with a follow-up phone call, to determine if there were any Native American concerns with the grazing program and if they would like to participate in the allotment assessment process. The communities either said that there were no impacts or decided not to comment / participate. None indicated a desire or need to participate in the assessment process. (Consultation log available for FY99)

Each of the tribal offices was contacted again by phone on 11/30/00 and the letter of January 1999 was sent to them again (fax). Several phone calls were made to each Tribe to follow up after they received the letter. Again, they stated that there are no impacts to their communities by the grazing program that could be construed as disproportionate impacts under the Environmental Justice criteria. (Consultation log available for FY2001)

A couple of the communities expressed some specific concerns that are addressed in the Native American Consultation section of the document.

Currently, the density of invasive, non-native plant species is low to moderate and is not affecting native species composition or vigor on the allotment except potentially for the rare annual species component, however no systematic monitoring of this relationship has occurred. Invasive species are also not contributing to other environmental impacts, such as fire hazard, increased erosion, or large-scale reductions in mychorrhizal densities (Bethlenfalvay and Dakessian 1984). Periodic monitoring (1-3 years) of the allotments will facilitate documenting changes in site composition and density of these non-native species.

B. Environmental Consequences

1. Impacts of Proposed Action

Provisions for grazing before seed set of these species has been included in allotment grazing stipulations. Early season grazing, normally before seed set, of these annual grasses may help reduce the spread of these invasives (Olson 1999) by reducing inputs into the seed bank of
particular sites. Other potential long-term impacts of the proposed action if weed densities increase include a reduction in native plant cover and vigor (below and above ground production), increased erosion leading to increased germination of invasive weed seed (Evans and Young 1972), and a reduction in mychorrizal populations. Currently, the cover value for these species is low on the majority of these allotments which will likely reduce the chance for rapid spread of these species if grazing timing stipulations are judiciously complied with.

2. No Grazing

No grazing before seed set of these invasive species could increase the seedbank inputs into particular sites overtime and potentially increase the density of some of these invasive, non-native species. However, no grazing would also reduce the chances that residual weed seed from sites is spread to new areas and would minimize the likelihood that the other long-term impacts discussed above would occur.

3. Cumulative Impacts

Cumulative impacts under the Proposed Action and No Grazing alternatives would include Off-highway vehicle (OHV) use that would exacerbate the spread of invasive weeds. However no unregulated OHV use was identified during the allotment assessments.

C. Consultation

Coordination with the California Native Plant Society, Bristlecone Chapter

NATIVE AMERICAN CONCERNS

A. Affected Environment

There are seven Native American communities in the Eastern Sierra. All of the communities are near, and in some cases even surrounded by, one or more allotments. None of the communities are living on an allotment. There are no treaty rights (hunting, fishing, etc.) associated with any of the communities or any of the allotments.

Some members of these communities hunt and some do some subsistence collecting of materials from public lands – pinyon nuts, basket weaving materials, medicinal plants, fire wood, etc. However, this is general use and there were no specific “traditional use areas” identified by any of the Tribes on any of the allotments. Any other traditional uses or use areas have not been divulged to this office.

Some general concerns mentioned by the Tribes are:

- They have general concerns with overgrazing and want us to control overgrazing to protect the ecosystem and ensure that it is functioning properly
- They have concerns that water (or other) developments not impact cultural sites and that they not affect deer habitat (through de-watering streams / springs, or trampling of habitat around new troughs, etc.)
- They do not want cattle grazing on top of individual burials or grave sites or within known Native American cemeteries
- They do not want sheep bedding on top of cultural sites
- They do not want BLM to use herbicides on plants that they might collect
- They do not want BLM to cut / remove pinyon

All project development proposals are examined for potential impacts prior to approval. This includes potential impacts to water sources, streams, wildlife habitat and cultural resources. This practice will continue under all alternatives.

Herbicides are used very sparingly and only in certain very restricted circumstances. Any potential application is examined for potential impacts prior to approval. This includes potential impacts to water sources, streams, wildlife habitat and cultural / traditional uses. This practice will continue under all alternatives.

There are no Pinyon in these allotments.

B. Environmental Consequences

1. Impacts of Proposed Action

The Assessment showed that there is no overgrazing in these allotments, that they are in proper
functioning condition. The intent is to keep the ecosystem functioning properly.

A cultural inventory and assessment is being done as part of the allotment assessment process. This cultural inventory and assessment will identify any current problems (water projects, fences, livestock bedding areas) causing impacts to cultural sites, including burials, so that they may be corrected.

2. No Grazing

Removing grazing would generally result in fewer impacts to the natural environment, thus alleviating the Native American concerns with overgrazing, water project development, grazing impacts to cultural resources/burial sites, etc.

3. Cumulative Impacts

The cumulative impacts of doing the allotment assessments and of issuing grazing permits within the requirements of the standards and guidelines will result in the long term protection and improvement of the ecosystems found within the jurisdiction of the Bishop Field Office – better habitats for plants and animals, protection of cultural sites, etc. These improvements, coupled with continued coordination and consultation with the Tribes, should result in BLM addressing the Tribes’ concerns in a manner agreeable to the Tribes.

C. Consultation

All seven Native American communities – Bridgeport, Mono Lake, Benton, Bishop, Big Pine, Ft. Independence, and Lone Pine – were contacted in January 1999 by letter, with a follow-up phone call, to determine if there were any Native American concerns with the grazing program and if they would like to participate in the allotment assessment process. The communities either said that there were no impacts or decided not to comment / participate. (Consultation log available for FY99)

Each of the tribal offices was contacted by phone on 11/30/00 and the letter of January 1999 was sent to them again (fax). Several phone calls were made to each Tribe to follow up after they received the letter. Various individuals stated some general concerns which are addressed above; but again, they stated that there are no direct specific impacts to their communities or to their community members by the grazing program. (Consultation log available for FY2001)

SOCIAL AND ECONOMIC VALUES

A. Affected Environment

Regionally livestock operations involve use of BLM, Forest Service (USFS), or City of Los
Angeles Department of Water & Power lands (LADWP). There are 5 permittees associated with the ten allotments. The Four J Cattle Company has permitted use for the Shannon Canyon/Baker Creek allotment (90 AUMs), the Black Mine allotment (47 AUMs), the Red Mountain allotment (304 AUMs), and the East Crater Mountain allotment (136 AUMs). The Spainhower Anchor Ranch contains a permit for the Ash Creek allotment (243 AUMs). Ronald C. Kemp has permitted use for the Alabama Hills allotment (1,364 AUMs) and the George Creek allotment (183 AUMs). Jack R. Tatum contains a permit for the Aberdeen allotment (231 AUMs) and for the Poverty Hills allotment (78 AUMs). Finally, William A. Beaver has a permit for the Blind Springs allotment (130 AUMs). There is a careful balance of head numbers and seasons of use, for grazing these allotments, such that any substantial change of use, would negatively affect their overall operation. Having other permits or lease land available does not in itself lead to increased flexibility.

The local economy is benefited by these grazing operations from monies spent to establish and maintain a ranching operation and contributions to the labor force. This is true of any privately owned business. Inyo and Mono County totaled $35,635,020 in agriculture production for 2000 which was an 8% increase from 1999. Inyo County agriculture ranks third, behind recreation/tourism and government agency operations, as an economic production sector. Of a 100% total in agricultural values, livestock production accounted for 51% in year 2000. This amounted to $7,438,970 or 51% of the total $14,481,970 agricultural production. In Mono County for year 2000, livestock production accounted for 47% of a 100% total in agricultural values. This amounted to $9,980,350 or 47% of the total $21,153,050 agriculture production. On a state-wide average, for every $1.00 in agricultural production, there is a $3.00 value to the economy.

B. Environmental Consequences

1. Impacts of Proposed Action

The local economy is benefited by these grazing operations from monies spent to establish and maintain a ranching operation and contributions to the labor force. Sustaining these operations, from continued use of BLM allotments, would have a positive economic affect on the stability of their overall livestock operation. The social value of retaining a rural, agricultural lifestyle would be preserved and would be in keeping with the public’s perception of the Owens Valley’s western culture. The proposed action will not impact the social and economic stability of these ranching operations.

2. No Grazing Alternative

If grazing were terminated on these BLM allotments, there would be slight to moderate impacts to both operators. The grazing capacity of their LADWP leases may not accommodate the increased use or meet LADWP’s management requirements of those lands. The permittees may be forced to operate with fewer cattle. There would be unauthorized grazing use onto BLM
lands, since their LADWP lease lands are unfenced. It would not be cost effective for LADWP to construct fences to contain cattle. The BLM may experience criticism resulting from this decision from its local constituency.

3. Cumulative Impacts

There will be no cumulative impacts from the proposed action.

SOILS

A. Affected Environment

The soil classification of the allotments has been mapped in detail by the Natural Resource Conservation Service (NRCS). Three main soil associations exist among the ten allotments, which are soils of Lava Flows, soils of the Mountainous Regions, and soils of the Stony Alluvial Fans. Allotments that contain soil of Lava Flows include Red Mountain, Aberdeen, and East Crater Mountain. Soils of Lava Flows are cinder loamy sands and sandy loams on basaltic lava flows and cinder cones. These soils are very deep and well to somewhat excessively drained. Available water capacity is low and the hazard of water erosion is moderate. Wind erosion hazard is slight. Allotments that contain soil of Mountainous Regions include Shannon Canyon/Baker Creek, Alabama Hills, Poverty Hills, and Blind Springs. Soils of the Mountainous Regions are primarily sandy loam, which are generally shallow to deep and well drained. Available water capacity is low to moderate. The hazard of erosion is slight to moderate for water and moderate to severe for wind. Because of the rapid intake and deep percolation of moisture, loss from runoff is negligible. This permits deep rooted plants to grow vigorously under arid conditions. These soils are highly susceptible to wind erosion if vegetation cover is removed. Allotments that contain soils of Stony Alluvial Fans include Black Mine, Ash Creek, and George Creek. Soils of the Stony Alluvial Fans are primarily gravelly loam, which are generally very deep and well drained. Alluvial fans are comprised of either shadscale gravelly loam or gravelly loams. These soils are mostly shallow, well drained, with gravelly to
cobbly surfaces and subsurface textures. These soils tend to limit the establishment of seeds and seedling development. Valley floor soils may also have inclusions of calcareous loam along remnant river terraces that exhibit duripans that inhibit water infiltration and restrict shrub rooting depths. Erosion potential of these soils range from slight to moderate on the valley floor due to wind erosion and can be somewhat attributable to the effects of cattle grazing and hoof action which disturbs the soil surface. The erosion potential on the alluvial fans is low due to the gravelly surface texture and low occurrence of cattle use compared with the valley floor. There are no identified erosion problems on the allotments.

BLM assessed these allotments in 2001 and 2002 to determine if the rangeland health standards were being met. Specific soils standards relate to permeability and infiltration. All sites examined were found to meet the standards for soils.

B. Environmental Consequences

1. Impacts of Proposed Action

The proposed action will create no new impacts.

2. No Grazing

The proposed action will create no new impacts.

3. Cumulative Impacts

There will be no cumulative impacts from the proposed action.

WATER QUALITY, SURFACE, AND GROUND WATER

A. Affected Environment

Perennial surface water occurs in 5 of the 10 grazing allotments in the form of streams and natural springs. The Black Mine, Aberdeen, Poverty Hills, East Crater Mountain and Blind Springs allotments are devoid of any permanent surface water sources on public land. The Shannon Canyon/Baker Creek allotment contains water only in the form of a few springs that have very little surface discharge and are located near Warren Bench that is typically not used by livestock. Water quality at spring 9-4-1C, the only source with perennial surface discharge, has never been determined.

Water quality for those allotments (Ash Creek, Alabama Hills, Red Mountain, and George Creek) with perennially flowing streams, based on a one time sampling, meets standards for aquatic life and primary drinking water standards for the following constituents: turbidity, dissolved oxygen, alkalinity (as CaCO₃), pH, CO₂ and total dissolved solids. Other constituents included in a comprehensive analysis for drinking water standards were not sampled.

In addition, the same streams were also sampled for their aquatic insect fauna (typically larval stages of insects). Some types of aquatic insects are typically found in streams with good water quality. Species of insects within the Ephemeroptera, Plecoptera and Trichoptera orders are representative of this condition. Sampling of the streams revealed that the number of individual species of aquatic insects occurred within the groups mentioned. Individual species (a few) were also found in the Diptera and Coleoptera orders of insects.

The available evidence suggests that water quality in the perennial streams is good.

B. Environmental Consequences

1. Impacts of Proposed Action

Water quality should be maintained, at a minimum, with implementation and monitoring of the proposed terms and conditions.

2. No Grazing

Water quality should be maintained, at a minimum, with implementation of a no grazing option.

3. Cumulative Impacts

Other impacts that have historically caused a temporary loss of water quality on small segments of some streams include vehicle travel at stream crossings along the Foothill Drive dirt road, uncontrolled application of heavy equipment at locations where the Los Angeles Department of
Water and Power have installed parschall flumes and installed/renovated water spreading structures (like on upper Shepherd Creek). While those activities have been detrimental to water quality over a short duration and in restricted locations, future effects from similar activities by the LADWP are controllable. Wildfires have caused a temporary decrease in water quality where riparian vegetation has been burned along a stream segment.

The temporary degradation of water quality is inevitable when vehicles use stream crossings and wildfires burn riparian vegetation. These events are not known to be detrimental to downstream water quality for any human or other biological interests. The proposed action should not contribute to any cumulative impact to water quality.

WETLANDS/RIPARIAN ZONES (CRITICAL ELEMENT)

A. Affected Environment

Streams

As examples for all other perennial streams within the allotments of concern, riparian vegetation along Ash Creek (Ash Creek allotment), Baker Creek (Shannon Canyon/Baker Creek allotment), George Creek (George Creek allotment) and Oak Creek (Alabama Hills allotment) is dominated by primary woody species such as willows: (Salix lutea, S. lasiolepis, S. exigua, S. goodingii, S. lucida), western water birch (Betula occidentalis), and wild roses (Rosa woodsii var. ultramontana). Herbaceous species are primarily comprised of sedges (Scirpus and Carex spp.) and rushes (Juncus spp.). Black oak (Quercus kellogii) and canyon live oak (Quercus chrysolepis) stands that occur along Ash, George, and Oak Creeks are anomalous components of eastern Sierra riparian vegetation. They are either remnant patches of the former Pliocene forests
of the interior or the result of the west-to-east acorn trade among native people of the Sierra (Taylor 1982).

Within the allotments of concern, the relatively narrow riparian widths of streams are driven by the geomorphology of alluvial fan dynamic processes. Despite the confined nature of these streams the condition of the riparian vegetation is good with regard to plant cover and composition. Along the majority of the stream miles vegetation is dense enough to discourage livestock access. Very few streams, like George Creek, have a combination of soil, vegetation and hydrology conditions interacting to meet Proper Functioning Condition (PFC) criteria (BLM 1998). George Creek also meets riparian Desired Plant Community (DPC) goals established by the 1993 RMP. The majority of streams in the area of concern, like Ash Creek, were determined to be Functioning at Risk (PFC) (BLM 1998) with an upward or no apparent trend. No PFC data exists for Baker and Oak Creeks. Although the majority of streams fall within the F-at-R category, the biological value and importance of this habitat type is central to the presence of a high diversity of plant and animal species across the total landscape (see additional discussion under Wildlife, below).

In the past several years (i.e. since approximately 1996) poor livestock management has caused the stream bank and bank vegetation conditions on portions of Braley Creek (Ash Creek allotment) to be degraded from trampling and over use of bank vegetation which has set the stream up for loss of vertical stability and a decrease in the capability to dissipate energy of higher flows. In recent years, there has been little to no use on Braley Creek. Vegetation has now been able to reestablish along the riparian corridor which will now stabilize banks and have the capability to dissipate energy during high flows.

Springs

Very few springs occur within the allotments of interest. Spring 9-4-1C on the north side of Warren Bench has a perennial discharge with relatively poor vegetation conditions due to camping and vehicle travel impacts at the source location. Surface discharge at other spring locations in this area and in the Black Mine allotment are typically sufficient to provide wet soil with no actual flow. Riparian vegetation is restricted at these sources to an area of approximately 0.02 acres and generally in excellent condition, except for a spring near Black Mine that is degraded due to a road.

B. Environmental Consequences

1. Impacts of Proposed Action

Implementation of the proposed action should maintain and/or slightly improve riparian vegetation conditions on the majority of streams by maintaining plant vigor, cover, and structure. These streams, except for a small portion of Ash Creek and all of Braley Creek, receive little to no livestock use because of their rocky and generally inaccessible terrain.
2. **No Grazing**

Proper Functioning Condition status would be restored to the small area of Ash Creek and all of Braley Creek within a few years of complete grazing exclusion. Conditions on the other streams would unlikely change from their current status due to little or no livestock use currently occurring on those channels.

3. **Cumulative Impacts**

Other impacts that have historically caused permanent loss or a temporary reduction in the amount and quality of riparian vegetation on small segments of some streams include road cuts across stream channels (like the Foothill Drive dirt road), uncontrolled application of heavy equipment at locations where the Los Angeles Department of Water and Power have installed parschall flumes or installed/renovated water spreading structures (like on upper Shepherd Creek). Occasional wildfires have caused a complete change in the seral stage of riparian vegetation (like along the entirety of Symmes Creek and a portion of Tuttle Creek in the Alabama Hills allotment).

The temporary degradation of water quality is inevitable when vehicles use stream crossings and wildfires burn riparian vegetation. These events are not known to be detrimental to downstream water quality for any human or other biological interests. The proposed action should not contribute to any cumulative impact to riparian conditions.

C. **Consultation**

No consultations were conducted with any person, group or agency.

Bishop Field Office, 1993 Assessment of Functional Condition on Streams, files.
A. Affected Environment

Uplands

Plant communities comprising the upland (non-riparian) areas are identified as mixed desert shrub, shadscale scrub, and sagebrush/bitterbrush. A 1978 wildlife inventory that employed a stratified random sampling scheme within these vegetation communities documented common small mammals, reptiles, and passerine songbirds that would typically be found in these habitat types.

Some of the small mammals documented in an ocular, live trapping and snap-trapping effort included black-tailed hare, Audubon cottontail rabbit, white-tailed antelope ground squirrel, Panamint kangaroo rat, long tail pocket mouse, canyon mouse, pinyon mouse, western harvest mouse, and desert wood rat. Coyote and gray fox are common mammalian predators in these habitats.

Reptiles of these habitat types include sagebrush lizard, side-blotched lizard, desert horned lizard, western whiptail, western fence lizard, gopher snake, speckled rattlesnake, Mojave rattlesnake, and sidewinder.

Birds likely to breed in these vegetation communities include black-throated sparrow, Brewer’s sparrow, sage sparrow, rock wren, blue-gray gnatcatcher, rufous-sided towhee, chipping sparrow, Say’s phoebe, Bewick’s wren, and house finch. The three sparrows are species of interest because they are considered sagebrush obligates and may be declining range-wide as a result of loss of sagebrush habitat, although in this area they are known to breed in other desert shrub communities. Upland game birds like chukar (non-native species), California quail, and mourning dove may reside and breed near water sources, in particular along the foothills of the White Mountains.

The area is used by winter resident raptors including Cooper’s hawk and rough-legged hawk, and breeding resident species including northern harrier, red-tailed hawk, golden eagle, prairie falcon, barn owl, and great horned owl.

Mule deer primarily use portions of the Alabama Hills, Ash Creek, Blind Springs, and George Creek allotments for winter range. The sagebrush/bitterbrush sites within these allotments provide critically important forage and cover for mule deer. Except for Blind Springs, water sources are readily available across these allotments. The water sources for mule deer on the Blind Springs allotment are artificial systems designed to provide sufficient water through winter months. Occasionally, deep snow conditions forces mule deer to move lower on the alluvial fans for the Owens Valley allotments and utilize other vegetation communities, however this is a rare event. Ensuring sufficient annual production (leader growth) is maintained on bitterbrush (an
essential food source for mule deer) after grazing by livestock is essential to survival of several hundred mule deer. This is especially true for the George Creek and Alabama Hills allotments.

Although not as numerous as mule deer, the Tule elk regularly utilize the George Creek and Alabama Hills allotments for most, if not all, of their seasonal habitat requirements. The Poverty Hills allotment, particularly the lava flow area immediately south of the Poverty Hills, is an elk calving area (occurring in the spring season). While elk may briefly use parts of some other allotments (like Black Mine, Red Mountain and East Crater Mountain), they are not dependent on those areas to meet nutritional or reproductive requirements. If available, elk prefer to consume herbaceous plant species (forbs and grasses), but they opportunistically forage on a cross section of grass, forb and shrub species the majority of the time. Elk food habits (which were very intensively analyzed in the 1972-1973 period) clearly show that the diversity of plant species they will utilize allows them to meet nutritional needs on almost any part of the allotments. For that reason, elk have been very successful in adapting to the habitat and anthropogenic induced conditions in the Owens Valley.

**Riparian**

The stream and spring environments (see Wetland/Riparian section above) provide highly productive habitat, of lesser acreage, for many of the species mentioned under the Upland areas. In addition, some songbird species are dependent on riparian vegetation communities for breeding, foraging or during migration. As an example, using the 1978 breeding bird survey information from the Bairs Creek riparian transect, songbirds associated with the west side Owens Valley streams include, but are not limited to, western wood pewee, black-headed grosbeak, Lazuli bunting, Costa’s hummingbird, black-chinned hummingbird, bushtit and warbling vireo. Due to the near absence of riparian sites on the east side of the Owens Valley, these and other riparian associated species are mostly absent.

Riparian habitat is scarce in the Owens Valley and of particular value to songbirds. Songbird use of Owens Valley alluvial fan riparian sites representative of these allotments were studied intensively from 1998-2000. Breeding bird diversity, species richness and numbers of individuals were lower than on sites at higher elevations or with broader riparian areas, but these sites did offer a variety of valuable riparian habitats as evidenced by the presence of several California Partners in Flight focal species, and dense nesting populations of three species of hummingbird. Egg laying began in late March and continued into July. Nest success was high or above average for most species, with exceptions including spotted towhee although this was the most abundant species. Predation was by far the most common reason for nest failure. Parasitism by brown-headed cowbirds was low, possibly reflecting remoteness from their foraging areas. These alluvial fan riparian habitats were found to be especially important to songbirds during spring and fall migration, and were also much used during the breeding season by some species such as sage and black-throated sparrow which nest in the upland nearby. An influx of predominantly higher-elevation nesting birds during heavy snow pack years and of
juvenile birds of species nesting at lower elevations demonstrates the use of these areas as dispersal corridors or spillover habitat for other adjacent habitats (Heath et al. 2001).

The importance of riparian habitat extends beyond the presence of songbirds. Stream shading, bank and channel stability, water quality, floodplain stability, habitat complexity, primary and secondary productivity, high plant and animal species diversity are a few of the attributes that riparian vegetation communities provide. Attributes relating to the physical conditions of riparian communities are responsible for their resilience against natural or man induced negative impacts, as long as the hydrologic conditions are not eliminated or severely curtailed. Riparian communities within the allotments are stable in the sense of a dependable annual hydrologic cycle, thus providing spatial and temporal continuity for a high diversity of plant and animal species over the larger landscape.

**Threatened or Endangered Species:**

No federally listed threatened or endangered species are known to occupy habitat within these allotments.

**B. Environmental Consequences**

1. **Impacts of Proposed Action**

The overall habitat quality of the allotments should be improved from their current conditions with implementation of the proposed terms and conditions. Species guilds like rodents and songbirds should reap the most immediate benefit from improvement in the availability of food resources and cover (particularly near or in riparian vegetation communities which are attractive to livestock concentrating their use).

2. **No Grazing**

Overall, wildlife habitat conditions would be improved, particularly in the immediate effects for species guilds like rodents. Granivorous rodents would likely benefit, over time, by an increased volume of seed producing plant species. A typical consequence would be a somewhat increased rodent population benefiting predatory species groups like canids and raptors. Other species guilds, like songbirds, should benefit from recovery of riparian vegetation, particularly on Braley Creek where restoration of a multilayered vegetation canopy would occur.

3. **Cumulative Impacts**

Historic impacts to the upland and riparian vegetation communities from road building, construction of water management facilities on some streams by the LADWP, location of campgrounds on private and public land, and wildfires have caused a permanent loss of vegetation (roads) or temporary change in seral condition (wildfires).
Improved condition in the native bunch grasses should provide an increased forage base for rodents and passerine birds across most allotments. To varying degrees, populations of these species should be improved in number of individuals, at least in the short term. Predator populations should also undergo an increase in numbers of individuals as a response to an improved prey base.

VEGETATION

A. Affected Environment

Uplands

A baseline range inventory for these allotments was completed in 1977 and correlated to the recently completed 1999 NRCS soil/vegetation inventory to document plant cover and composition as well as develop updated ecological site descriptions. The allotments occur in the Great Basin and Northern Mojave Floristic Provinces. The dominant plant communities are mixed desert scrub, shadscale scrub and sagebrush/bitterbrush. Shadscale scrub is dominated by shadscale (Atriplex confertifolia) and budsage (Artemisia spinescens) with a sparse (15% or less) understory of desert needlegrass (Achnatherum speciosum) and Indian rice grass (Achnatherum hymenoides) (Barbour and Major 1977). Additional species include, but are not limited to: hop sage (Grayia spinosa), horsebrush (Tetradymia canescens and T. axillaris), Nevada ephedra.
(Ephedra nevadensis), winter fat (Krasheninnikovia lanata), yellow rabbitbrush (Chrysothamnus naseosus), green rabbitbrush (Chrysothamnus teretifolius), gold bush (Ericameria cooperi), and cheesebush (Hymenoclea salsola). During years of high precipitation, annual forbs are abundant and include species from the following genera: Cryptantha, Mentzelia, Linanthus, Phacelia, as well as genera in the Asteraceae Family.

The sagebrush/bitterbrush communities that comprise small portions of the George Creek, Shannon Canyon/Baker Creek, Alabama Hills, Aberdeen and Blind Springs Allotments contain sagebrush (Artemisia tridentata ssp. tridentata and Artemisia tridentata ssp. wyomingensis (Blind Springs Allotment), bitterbrush (Purshia tridentata var. glandulosa and P. tridentata ssp. tridentata component. Understory grasses such as desert needlegrass (Achnatherum speciosum), and Indian rice grass (Achnatherum hymenoides) can make up 15-20% of the cover at the higher elevations of the alluvial fans.

The majority (80-90%) of the upland plant communities within these allotments have not been significantly impacted by livestock grazing because of the infrequent use and low number of animals that make use of these allotments as well as the general topography and rough terrain which reduces livestock access. Generally, utilization of key forage species, e.g. desert needlegrass, hopsage, winterfat, budsage, and bitterbrush is slight to moderate and occurs in spring (March-early May). Forage capacity on these allotments is low and the plant communities are incapable of sustaining large numbers and frequent livestock use which has been shown to be detrimental to the various attributes of ecological function including plant vigor, seedling recruitment, and recovery (Clary and Holmgren 1987; Hughes 1982).

B. Environmental Consequences

1. Impacts of Proposed Action

Impacts of the Proposed Action on the vegetation within these allotments is directly effected by grazing timing, intensity, and stocking rates. Current stocking rates are moderate and do not significantly impair the large-scale ecological function of these plant communities during non-drought years. Grazing does occur in spring which has been shown to increase shadscale (Atriplex confertifolia) and reduce bud sage (Artemisia spinosa) densities at moderate to high grazing intensities (Clary and Holmgren 1987). The key forage species which receive the most use at spring turn-out are the perennial bunch grasses. Continued grazing at current levels will affect very small portions (in the vicinity of water troughs and mineral blocks) of the allotments and not contribute to reductions in overall plant community ecological function as long as current Rangeland Health Guidelines are adhered to, e.g. 40% utilization. There may be increases in invasive weeds in proximity to high concentration use areas e.g. watering facilities and mineral blocks.
2. No Grazing

Under the No Grazing alternative, positive results to the ecological function (i.e. plant vigor) of these plant communities would occur.

3. Cumulative Impacts

Cumulative impacts may include changes in Department of Water and Power allotment management which could prompt permittees to seek out more grazing opportunities on Public Land.

FINDING OF NO SIGNIFICANT IMPACTS

I have reviewed this environmental assessment including the explanation and resolution of any potentially significant environmental impacts. I have determined that the proposed action will not have any significant impacts on the human environment and that an EIS is not required.

There will be no effect on threatened or endangered species as a result of the action.

I have determined that the proposed project is in conformance with the Bishop Resource Management Plan, which was approved March 25, 1993. This plan has been reviewed, and the proposed action conforms with the land use plan terms and conditions as required by 43 CFR 1610.5.

Furthermore, it is my decision to implement the proposed action and issue 10-year grazing permits with the currently used standard grazing stipulations to the grazing operators for the other ten allotments. Livestock grazing management on these ten allotments will remain unchanged from past use, but subject to adherence with the Central California Rangeland Health Standards and Guidelines and RMP decisions pertaining to livestock use. The Rangeland Health Assessments conducted, indicate that there are no significant environmental impacts from current use and the allotments all meet the Rangeland Health Standards.
