1.0 INTRODUCTION

1.1 Background

The Bureau of Land Management (BLM) Colorado State Office (COSO) completed the first iteration of the Colorado Air Resources Management Modeling Study (CARMMS 1.0) in early 2015. In this study, projected year 2021 regional air quality and related value impacts were modeled using the West-wide Jump-start Air Quality Modeling Study (WestJUMPAQS) year 2008 modeling platform. Results were published in a January 2015 report: "Colorado Air Resources Management Modeling Study (CARMMS), 2021 Modeling Results for the High, Low and Medium Oil and Gas Development Scenarios" (ENVIRON et al., 2015). This CARMMS 1.0 study included analysis of the air quality (AQ) and air quality related value (AQRV) impacts of oil and natural gas development and mining emissions in the planning areas of individual BLM field offices in Colorado and cumulative AQ and AQRV impacts due to non-Federal oil and gas and mining sources and other regional sources. The Mancos Shale oil and gas development area in north-western New Mexico is adjacent to some of the Colorado BLM Planning Areas and was also included in the CARMMS 1.0 analysis.

The BLM New Mexico State Office funded an intermediate iteration of CARMMS (CARMMS 1.5) that included additional updates to the Mancos Shale inventory and other updates to CARMMS 1.0 such as the consideration of the October 2015 ozone National Ambient Air Quality Standard (NAAQS) of 0.070 ppm. Results were published in a March 2016 report entitled "Colorado Air Resources Management Modeling Study (CARMMS) with Updated Mancos Shale Modeling: 2021 Modeling Results for the High, Low and Medium Oil and Gas Development Scenarios, CARMMS 1.5" (Ramboll Environ and Kleinfelder, 2016a).

Several current Resource Management Plans (RMPs) leverage CARMMS for planning area specific and cumulative future air quality predicted results. These RMPs cover planning for resource management and land-use in Colorado up to 20 years into the future. To support the RMPs and to support other BLM needs, BLM conducted the second iteration of CARMMS (CARMMS 2.0) that will project year 2025 regional air quality using a year 2011 modeling platform with updated information such as new oil and gas reasonable foreseeable development (RFD) estimates for year 2025.

1.2 Purpose

This document presents the approach and results for the CARMMS 2.0 High, Low and Medium Development Scenarios source apportionment modeling and analysis. Presented are the individual AQ and AQRV impacts due to projected BLM-authorized mineral development activities in Field Office planning areas and other cumulative sources. The 2025 modeling results are compared with NAAQS and State Ambient Air Quality Standards (SAAQS) throughout the 12/4 km modeling domain. The contributions of O&G development to AQ and AQRV at Class I and sensitive Class II areas are presented and compared to PSD increment concentrations and visibility and deposition thresholds of concern. Cumulative peak-weighted index (W126) ozone values are also calculated and analyzed for the 2011 Base Year and the 2025 High, Low, and Medium Scenarios.

1.3 Overview of Modeling Approach

The Comprehensive Air Quality Model with Extensions (CAMx) photochemical grid model (PGM) (www.camx.com) is used in CARMMS 2.0 to assess the AQ and AQRV impacts associated with BLM-authorized mineral development on Federal lands within BLM Colorado and the New Mexico Farmington Field Office Planning Areas. CARMMS does not assess the near-source AQ impacts of the O&G and other development activities; those will be addressed at the Project level in the future. The development of a PGM database is quite resource-intensive. Thus, to the extent possible and similar to CARMMS 1.0 and CARMMS 1.5, CARMMS 2.0 leveraged the modeling platform of Western Air Quality Study (WAQS) from the Intermountain West Data Warehouse (IWDW) (views.cira.colostate.edu/tsdw/).

The CARMMS 2.0 CAMx modeling of the 12/4 km modeling domains (Figure 2-1) for a 2025 future year emission scenario using the IWDW WAQS meteorological inputs involved the following activities:

- Future year O&G emissions were developed for a range of potential outcomes which attempt to bound actual future year O&G development in the region. Three 2025 future year O&G development scenarios were modeled within Colorado Planning Areas, the Mancos Shale, and Southern Ute Indian Tribe (SUIT) lands:
  - High Development Scenario;
  - Low Development Scenario; and
  - Medium Development Scenario, which is a mitigated version of the High Development Scenario.

  There are four general types of future year emissions addressed in CARMMS:

  1. BLM-authorized (Federal lands) and other (non-Federal lands) oil and gas and mining emissions within the Colorado BLM planning areas (as well as the BLM Farmington Field Office in northern New Mexico);
  2. Oil and gas and other development areas outside Colorado/northern New Mexico BLM Planning Areas;
  3. Remaining future year anthropogenic emissions; and
  4. Emissions that remained unchanged from the base year in future year scenarios.

- The future year emissions were processed using the SMOKE (Sparse Matrix of Kernel Emissions) system to generate 2025 emissions for the CARMMS 2.0 12/4 km domains.
- 2025 Boundary Condition (BC) inputs for the CARMMS 2.0 12 km modeling domain were generated using output from the 2025 WAQS 12 km CAMx model simulation using the 2011 meteorological inputs.

- CAMx ozone and particulate matter source apportionment simulations were performed for the 2025 High, Low and Medium Development Scenarios and 12/4 km CARMMS 2.0 modeling domains using the 2011 CARMMS 2.0 modeling platform.
    - The CAMx 2025 12/4 km CARMMS 2.0 domains source apportionment output for the High, Low and Medium Development Scenarios were post-processed to obtain the separate AQ and AQRV impacts due to mineral development activities on Federal lands within the BLM New Mexico FFO planning area and each of the 13 Colorado BLM planning areas.
    - The CAMx 2025 High, Low and Medium O&G Development Scenarios output was also post-processed to obtain the cumulative AQ and AQRV impacts due to mineral development on Federal and non-Federal lands within the BLM New Mexico FFO (NMFFO) planning area and 12 BLM planning areas in Colorado, plus SUIT, as well as O&G development throughout the CARMMS 2.0 12/4 km modeling domain.
    - In addition to the CAMx source apportionment simulation, another CAMx simulation that used zero emissions from new Federal O&G in BLM Planning areas in Colorado was conducted for each of the three scenarios to assess their AQ and AQRV impacts with a Brute-Force approach, and the results were compared to the source apportionment results.
- The AQ and AQRV impacts of BLM-authorized oil and gas development on Federal lands in each BLM Colorado planning area and the NMFFO area and cumulative impacts across all planning areas for the 2025 High, Low and Medium Development Scenarios are summarized in this report.

1.4 Air Quality Standards and AQRV Thresholds

1.4.1 Federal and State Air Quality Standards and PSD Increments

EPA sets NAAQS for six pollutants, which are called criteria air pollutants (CAPs). The CAPs are: ozone (O_3), nitrogen dioxide (NO_2), carbon monoxide (CO), suspended Particle Pollution (particulate matter with a mean aerodynamic diameter of less than or equal to 10 and 2.5 microns; PM_{10} and $PM_{2.5}$), sulfur dioxide (SO_2) and lead (Pb). States may also set their own ambient air quality standards, which must be as stringent as the NAAQS but may be more stringent.

Federal air quality regulations adopted and enforced by the states limit incremental emission increases to specific levels defined by the classification of air quality in an area. The Prevention of Significant Deterioration (PSD) Program is designed to limit the incremental increase of specific air pollutant concentrations above a legally defined baseline level. Incremental increases in PSD Class I areas are strictly limited, while increases allowed in Class II areas are less strict. PSD Class I and Class II increments are defined for NO_2, PM_{10}, $PM_{2.5}$ and SO_2. Note the PSD increments are project level thresholds, and are not an appropriate metric for reference against field office level impacts.

Table 1-1 summarizes the NAAQS, the Colorado Ambient and Quality Standards (CAAQS) and the New Mexico Ambient Air Quality Standards (NMAAQS). PSD Class I and Class II increments are also shown in Table 1-1.

Table 1-1. Applicable National and State Ambient Air Quality Standards and PSD concentration increments.

Pollutant/Averaging Time	NAAQS	CAAQS[13]	NMAAQS[14]	PSD Class I Increment[1]	PSD Class II Increment[1]
CO					
1-hour[2]	35 ppm	--	13.1 ppm	--	--
8-hour[2]	9 ppm	--	8.7ppm	--	--
NO_2					
1-hour[3]	100 ppb	--	--	--	--
24-hour	--	--	0.10 ppm	--	--
Annual[4]	53 ppb	--	0.05 ppm	2.5	25
O_3[15]					
8-hour[5]	0.070 ppm	--	--	--	--
PM_{10}					
24-hour[6]	150 µg/m^3	--	--	8	30
Annual[7]	--	--	--	4	17
$PM_{2.5}$					
24-hour[8]	35 µg/m^3	--	--	2	9
Annual[9]	12 µg/m^3	--	--	1	4
SO_2					
1-hour[10]	75 ppb	--	--		
3-hour[11]	0.5 ppm	700 µg/m^3	--	25	512
24-hour[12]	--	--	0.10 ppm	5	91
Annual[4]	--	--	0.02 ppm	2	20

1. The PSD demonstrations serve information purposes only and do not constitute a regulatory PSD increment consumption analysis.
2. No more than one exceedance per calendar year; for NMAAQS - No more than one exceedance per consecutive 12 months
3. 98th percentile, averaged over 3 year; for NMAAQS - not to be exceeded more than once over any 12 consecutive months
4. Annual mean not to be exceeded; for NMAAQS - arithmetic average over any four consecutive quarters not to be exceeded
5. Fourth-highest daily maximum 8-hour ozone concentrations in a year, averaged over 3 years
6. Not to be exceeded more than once per calendar year on average over 3 years.
7. 3 year average of the arithmetic means over a calendar year
8. 98th percentile, averaged over 3 years
9. Annual mean, averaged over 3 years, NAAQS promulgated December 14, 2012
10. 99th percentile of daily maximum 1-hour concentrations in a year, averaged over 3 years
11. No more than one exceedance per calendar year (secondary NAAQS) and no more than one exceedance in 12 consecutive months (CAAQS)
12. For areas in New Mexico not within 3.5 miles of the Chino Mines Company

15. Finalized on October 1, 2015.

1.4.2 Air Quality Related Value (AQRV) Thresholds

The impacts of each BLM authorized oil and gas and other activities within each BLM Planning area, as well as cumulative impacts of all activities together, at Class I and sensitive Class II areas were assessed for three AQRVs: visibility, deposition and acid neutralizing capacity (ANC). The June 23, 2011 MOU between EPA, USDOI and USDA states that the project and cumulative AQRV impacts at Class I and sensitive Class II areas should be assessed by comparing against thresholds of concern defined by the Federal Land Manager (FLM) for the given Class I or sensitive Class II area in question. In the CARMMS first draft Modeling Protocol and at the October 30, 2013 meeting with the Interagency Air Quality Review Team (IAQRT) we presented the following threshold of concern for AQRVs in Class I and sensitive Class II areas and there were no disagreements in the comments received from the IAQRT:

Visibility impacts for BLM-authorized oil and gas sources within each BLM Planning Area are assessed using the FLAG (2010) procedures that use the new IMPROVE equation, annual average natural visibility background and monthly relative humidity adjustment factors [f(RH)] (see Section 4.6.1). The visibility impacts from mineral development on Federal lands within each separate BLM planning area are compared against a 0.5 and 1.0 change in deciview (dv) haze index threshold of concern and any exceedances reported. We note the dv thresholds are project level thresholds, and not an appropriate metric to reference against field office level or cumulative impacts.

Cumulative sources visibility impacts from multiple BLM Planning Areas are assessed using a new visibility approach and metrics developed by the FLMs based on the regional haze rule visibility metrics for the best and worst 20% visibility days as discussed in Section 4.6.2.

Acid deposition impacts due to mineral development on Federal lands within each separate BLM Planning Area for annual total sulfur (S) and total nitrogen (N) deposition are compared against the 0.005 kg/ha-yr Deposition Analysis Threshold (DAT) for the western states. We note the DAT is a project level threshold, and not an appropriate metric to reference against field office level or cumulative impacts.

Total N and S deposition impacts due to all emissions in the 2011 and 2025 emissions scenarios (i.e., cumulative) are compared to Critical Load values of 2.2 kg/ha-yr for N in Wyoming, 2.3 kg/ha-yr for N in Colorado except for Dinosaur National Monument where a 3.0 kg/ha-yr Critical Load value for N is used. For S, a 5.0 kg/ha-yr critical load value is used everywhere (see Section 4.7).

The predicted annual deposition fluxes of sulfur and nitrogen at sensitive lake receptors due to Federal O&G development from individual BLM Planning Areas are used to estimate the change in ANC in accordance with the January 2000, USFS Rocky Mountain Region's Screening Methodology for Calculating ANC Change to High Elevation Lakes, User's Guide (USFS, 2000). The predicted changes in ANC are compared with the USFS's Level of Acceptable Change (LAC) thresholds of 10% for lakes with ANC values greater than 25 µeq/l and 1 µeq/l for lakes with background ANC values of 25 µeq/l and less (see Section 4.8). We note that the LAC is a project level threshold, and not an appropriate metric to reference against field office level or cumulative impacts.

1.4.3 W126 Cumulative Ozone Exposure Assessment

Although there is no adopted standard to assess the potential vegetation response to ozone as a stress to growth, there has been interest expressed in assessing such an effect with the W126 metric, and such an assessment is included herein. The methodology is discussed in Section 4.9.

2.0 CARMMS 2.0 MODELING APPROACH

The photochemical grid model was applied in CARMMS 2.0 to assess the AQ and AQRV impacts associated with BLM-authorized mineral development on Federal lands within BLM Colorado and the New Mexico Farmington Field Office Planning Areas as well as other cumulative non-Federal sources. CARMMS 2.0 uses data from the modeling platform of Western Air Quality Study (WAQS) from the Intermountain West Data Warehouse (IWDW) for the 2011 base year and 2025 future year air quality modeling.

The CARMMS 2.0 approach was designed to leverage the WAQS-IWDW modeling platform to the largest extent possible, for efficient preparation of input data for the CARMMS 2.0 modeling, and to eliminate the need for a comprehensive model performance evaluation, since the WAQS modeling has already gone through a comprehensive MPE (UNC and Ramboll Environ, 2016). However, due to a few changes made in the CARMMS 2.0 modeling compared to the WAQS platform as discussed below, an abbreviated MPE was conducted to check for equivalency with the WAQS results (see Section 2.4).

There are two main differences between CARMMS 2.0 and the WAQS-IWDW modeling platform, namely the modeling domain and the CAMx model version. It is not computationally practical to run the WAQS-IWDW modeling platform as is for CARMMS, so a subset of the domain is selected for CARMMS 2.0 (Figure 2-1) to reduce the computational burden of the CAMx source apportionment runs for the three 2025 future year cases for the high, medium and low oil and gas scenarios. CARMMS 2.0 uses CAMx version 6.20 while WAQS applied version 6.10. Through test runs, we confirmed that the change in CAMx version from 6.10 to 6.20 does not introduce notable changes in the modeling results for ozone and $PM_{2.5}$ in this domain.

2.1 CAMx Modeling Domains

CARMMS 2.0 adopted a two-way nested 12/4 km horizontal resolution domain as shown in Figure 2-1. Because the southern boundary of the IWDW WAQS 2011 4 km air quality domain does not extend as far south into New Mexico as the CARMMS 1.0 4 km domain (Figure 2-2), the central part of New Mexico was modeled at 12 km resolution in CARMMS 2.0 while all of Colorado and northern New Mexico (including the Farmington Field Office) was modeled at 4 km resolution (Figure 2-1). The grid projection is the standard Regional Planning Organization (RPO) Lambert Conformal Conic projection also used in CARMMS 1.0 and 1.5, with true latitudes at 33°N and 45°N and centered at 40°N, 97°W. The datum (size and shape of earth) is a perfect sphere with radius 6370.0 km.

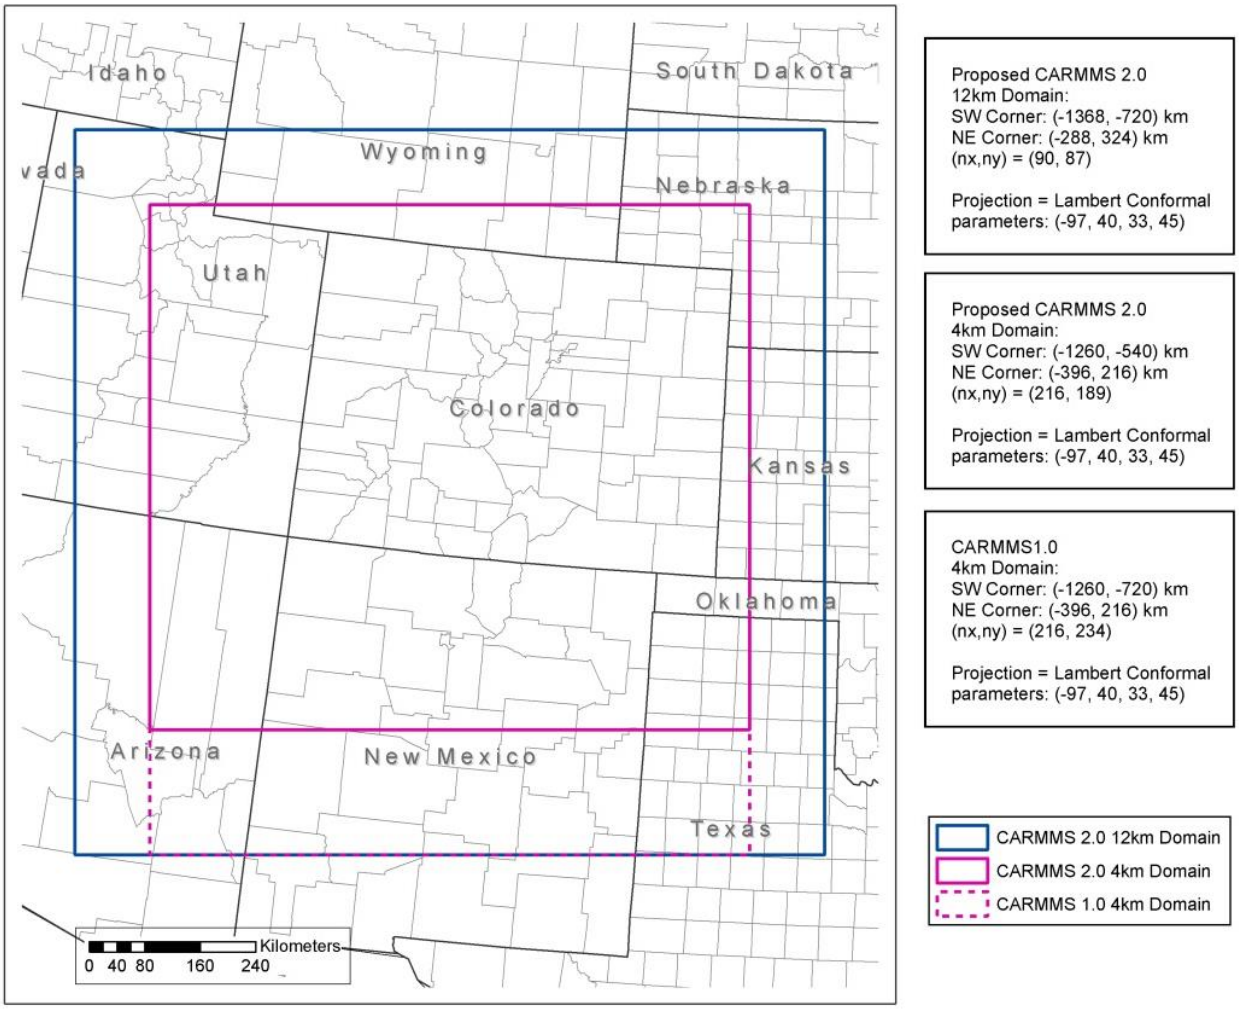

Figure 2-1. CARMMS 2.0 12/4 km air quality modeling domains (CARMMS 1.0 domain also shown for reference).

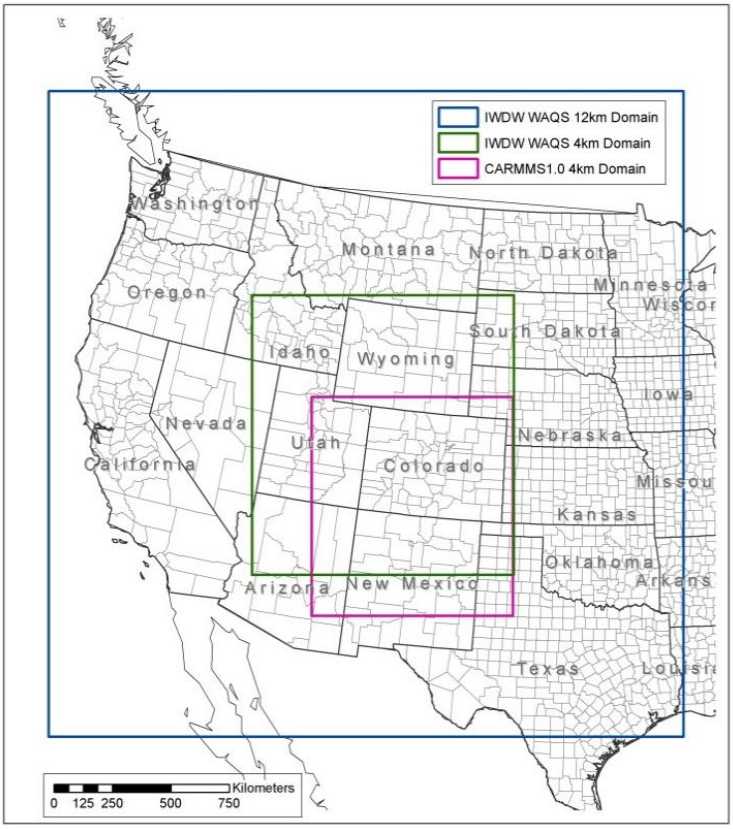

Figure 2-2. IWDW WAQS 2011 12 km (blue) and 4 km (green) and CARMMS 1.0 4 km (pink) air quality modeling domains.

In WAQS, WRF was applied with 37 vertical levels (36 vertical layers using the CAMx definition of layer thicknesses) from the surface up to 50 mb (approximately 19 km high above mean sea level) (http://views.cira.colostate.edu/tsdw/). The WRF model employs a terrain following coordinate system defined by pressure. Table 2-1 shows the mapping between the WRF vertical layers and the 25 vertical layers in CAMx for WAQS and CARMMS 2.0.

Table 2-1. 37 Vertical layer interface definition for WAQS WRF simulations (left most columns), and approach for reducing to 25 vertical layers for CAMx in CARMMS 2.0 by collapsing multiple WRF layers (right columns).

WRF Meteorological Model					CAMx Air Quality Model		
WRF Layer	Sigma	Pressure (mb)	Height (m)	Thickness (m)	CAMx Layer	Height (m)	Thickness (m)
37	0.0000	50.00	19260	2055	25	19260.0	3904.9

2.2 Modeling Configuration and Inputs

A prior version of CAMx (v6.1) was run in CARMMS 1.0 and CARMMS 1.5. In CARMMS 2.0, a later version (v6.20) was applied with the Carbon Bond 6 revision 2 (CB6r2) photochemical mechanism. Table 2-2 summarizes the model configurations and options used in CARMMS 2.0 modeling.

Table 2-2. Summary of CAMx Model Configuration for CARMMS 2.0.

Science Options	Configuration
Model Code Version	CAMx V6.20
Horizontal Grid	12/4 km
12 km grid	90 x 87 cells
4 km grid	216 x 189 cells
Vertical Grid	25 vertical layers
Grid Interaction	12/4 km two-way nesting
Initial Conditions	Clean initial conditions with 10-day spin-up
Boundary Conditions	12 km BCs from 2011 WAQS 12km simulation
Land-use Data	Land-use fields based on USGS GIRAS data
Photolysis Rate Preprocessor	TUV V4.8 (Clear-sky photolysis rates from TOMS data)

Science Options	Configuration
Gas-phase chemistry	CB6r2
Aerosol-phase	CF (coarse and fine mode aerosols)
Diffusion Scheme	
Horizontal-grid	Explicit horizontal diffusion
Vertical-grid	K-theory 1st-order closure
Deposition Scheme	
Dry deposition	ZHANG03
Wet deposition	CAMx-specific formulation
Numerical Solvers	
Gas-phase chemistry	Euler Backward Iterative (EBI) solver
Horizontal advection	Piecewise Parabolic Method (PPM)
Vertical advection	Implicit scheme with vertical velocity update

Input data for emissions, meteorology, land use, and initial and boundary conditions for CARMMS 2.0 2011 base year modeling were prepared using data from the WAQS 2011b platform archived by IWDW. Specifically, the merged emission files for the 12 and 4 km WAQS air quality domains from the IWDW database were "windowed" to prepare CAMx-ready emissions for the CARMMS 2.0 12/4 km domain for Year 2011 modeling. Prior to CARMMS 2.0, an error was found in the lightning NOx emissions used in WAQS 2011b modeling; this error was fixed in the merged point source emission files used for CARMMS 2.0 modeling. Meteorological inputs and land use files for the CARMMS 12 km and 4 km modeling domains were windowed from the CAMx-ready WRFCAMx inputs used for WAQS 12 km and 4 km domains, respectively. Initial and boundary conditions for the CARMMS 2.0 12 km domain were extracted from 3-D modeling outputs from WAQS 2011b 12 km domain modeling. 12 km 3-D outputs from the 2025 WAQS modeling were used to generate initial and boundary conditions for the CARMMS 2.0 2025 future year source apportionment modeling. Photolysis rates for input to CAMx were calculated using the Tropospheric visible Ultra-Violet (TUV) model developed by the National Center for Atmospheric Research (Madronich, 1993).

2.3 2011 Base Case Emissions

The CARMMS 2.0 2011 base case emissions were "windowed" (i.e., a smaller spatial extent) and extracted from the final Western Air Quality Study (WAQS) 2011b Base Case emissions to generate CAMx-ready emissions for the CARMMS 2.0 12/4 km domain. The primary source for the WAQS 2011b Base Case emissions is Version 2 of the 2011 National Emissions Inventory (NEI2011v6.2[1]). For most source categories, the SMOKE emissions modeling system was used to process the emissions into the hourly gridded speciated emissions needed as input for CAMx. Table 2-4 summarizes the emission models and sources of the WAQS 2011b base year emissions. The comprehensive and detailed documentation for the WAQS 2011b Base Case

[1] http://www.epa.gov/ttnchie1/net/2008inventory.html

emissions inventory is available on the IWDW website[2] and EPA's Technical Support Document for the 2011v6.2 platform[3].

On-Road Mobile Sources: The Motor Vehicle Emissions Simulator (MOVES) is EPA's current tool to construct on-road mobile source emissions estimates for national, state, and county level inventories of criteria air pollutants, greenhouse gas emissions, and some mobile source air toxics from highway vehicles. For all states except California, MOVES2014 was run for WAQS 2011b to generate 2011 emission factors, which were then used by SMOKE-MOVES to develop model-ready emissions. In Colorado, the on-road refueling emissions were replaced by the state submitted point emissions.

Non-Road Mobiles Sources: For non-road mobile sources, county-level inventory was directly taken from the NEI non-road sector. For all states except California and Texas, non-road mobile equipment emissions were developed with the National Mobile Inventory Model (NMIM) using NONROAD2008 version for WAQS 2011b.

Point Sources (CEM and non-CEM point): For the WAQS 2011b platform, 2011 hourly NO_x and SO_2 emissions for Continuous Emissions Monitor (CEM) sources were obtained from the Clean Air Markets Division (CAMD); other pollutants for CEM sources and non-CEM and non-oil and gas point sources were directly taken from the NEI platform.

Area Sources: The Area (or Non-Point) data category contains emission estimates for sources which individually are too small in magnitude or too numerous to inventory as individual point sources, and which can often be estimated more accurately as a single aggregate source for a County or Tribal area. Area source (non-point) emissions are emissions sources that are summed over a geographic region, rather than specifically located. Examples of area sources include small industrial, residential, consumer product, and agricultural emissions. In the WAQS 2011b Base Case platform, emission inventory from these area sources were directly taken from 2011 NEI platform. For fugitive dust emissions, post-hoc adjustments were applied to account to vegetation scavenging. A meteorology-based algorithm was applied to emissions from fertilizer and residential wood combustion sources to simulate the temporal variability in hourly and daily emissions, respectively. For aircraft, locomotive and marine sources, county-level inventory was also from the NEI platform.

Oil and Gas Sources: For basins covered by the 2011 3SAQS Phase II inventory, including the Denver-Julesburg, Piceance, Uintah, North San Juan, South San Juan, Southwest Wyoming, Wind River, Powder River, Big Horn, Paradox, Raton, and Williston basins, the 2011 3SAQS Phase II inventory was used. Detailed updates to the 2011 3SAQS Phase II inventory is available

[2] http://vibe.cira.colostate.edu/wiki/wiki/2078
[3] https://www.epa.gov/sites/production/files/2015-10/documents/2011v6_2_2017_2025_emismod_tsd_aug2015.pdf

on the IWDW website[4]. For basins not covered by the 2011 3SAQS Phase II inventory, the NEI inventory was used.

Natural Emissions: The latest version of MEGAN (version 2.1) was used to simulate biogenic emissions using the WAQS 2011 meteorology. Emissions from wild fires, prescribed burns and agricultural burning were based on the Particulate Matter Deterministic and Empirical Tagging and Assessment of Impact on Levels (PMDETAIL) 2011 version 2 inventory. Wind-blown dust emissions were from the WRAP dust model[5] with 2011 meteorology. Lightning NOx emissions were generated based on the modified model of Koo et al. (2010) used in the WestJumpAQMS. Sea salt emissions were calculated by an emission processor for use with CAMx.

2.4 Abbreviated Base Year Model Performance Evaluation

The CARMMS 2.0 base year 2011 modeling bears high consistency with the IWDW WAQS 2011b platform, with the only known differences being (1) the model version, (2) the lightning NOx point source emissions, and (3) the difference in model resolution for areas to the north and west of the CARMMS 4 km domain, which were simulated at 12 km resolution in CARMMS 2.0 and at 4 km resolution in WAQS. The extensive use of modeling data from WAQS-IWDW has significantly improved the efficiency of CARMMS 2.0 air quality modeling. Results from the abbreviated CARMMS 2.0 MPE indicate that the modified modeling platform for CARMMS 2.0 shows approximately equivalent model performance with the WAQS-IWDW 2011b modeling platform and also meets relevant goals and criteria for ozone and $PM_{2.5}$ in general. More details of the abbreviated Base Year MPE are provided in Appendix A.

Table 2-4. Summary of sources of emissions and emission models used to generate WAQS 2011b base case emissions for use in CARMMS 2.0

Emissions Component	Configuration	Details
Oil and Gas Emissions	Updated 2011 3AQS Phase II inventory and NEI 2011v2	2011 3SAQS Phase II inventories for the Denver-Julesburg, Piceance, Uintah, North San Juan, South San Juan, Southwest Wyoming, Wind River, Powder River, Big Horn, Paradox, Raton, and Williston basins; for basins not covered by the 2011 3SAQS Phase II inventory, use NEI emissions.
Area Sources Emissions	NEI 2011v2	County-level inventory taken directly from the NEI. Post-hoc adjustments applied to dust emissions to account for vegetation scavenging; meteorology-based algorithm applied to fertilizer and residential wood combustion emissions to simulate the temporal variability in hourly and daily emissions.
On-Road Mobile Emissions	NEI 2011v2	EPA ran MOVES2014 for 2011 in emissions factor mode. The MOVES lookup tables include on-network (RPD), on-network refueling (RPD_RFL), on-network for CA (RPD_CA), off-network starts/stops (RPV), off-network starts/stops refueling (RPV_RFL), off-network starts/stops for CA (RPV_CA), off-network vapor venting (RPP) off-network vapor venting sources for CA (RPP_CA), and extended idling (RPH). These data include the reference county and reference fuel month assignments that EPA used for the MOVES simulation. The CA MOVES estimates were normalized to emissions values provided by CARB.
Off-Road Mobile Emissions	NEI 2011v2	County-level inventories taken directly from the NEI for recreational vehicles, logging equipment, agricultural equipment, construction equipment, industrial equipment, lawn and garden equipment, leaf and snow blowers, and recreational marine. The CA and TX NONROAD estimates were normalized to emissions values provided by these states.
Point Sources Emissions	2011 CEM and NEI 2011v2	2011 Clean Air Markets Division (CAMD) hourly NO_x and SO_2 emissions for CEM sources and county-level inventory taken directly from the NEI for other pollutants and non-CEM and non-oil and gas point sources.
Fires	PMDETAIL 2011 version 2	PMDETAIL 2011 version 2 inventory for wild, prescribed, and agricultural fires in the U.S., Canada, and Mexico; includes pre-computed plume parameters and speciated PM.
Biogenic Sources	MEGAN	MEGAN v2.10 biogenic emissions calculated using the WAQS 2011 meteorology
Wind-Blown Dust Emissions	WRAP wind-blown dust model	WRAP wind-blown dust emissions calculated using the WAQS 2011 meteorology
Sea Salt Emissions	Emissions processor	Sea salt emissions
Lightning Emissions	Modified Lightning NO_x emissions model	Lightning NO2 emissions

3.0 FUTURE YEAR EMISSIONS

In this section, we describe the development of the future year emissions scenario. The future year emissions scenario modeled is 2025. Forecasting future year oil and gas (O&G) emissions has many uncertainties because future O&G emissions depend on economic conditions (e.g., price of natural gas and oil), identification of new O&G plays, availability of exploration and development equipment and regulatory requirements. For CARMMS, future year O&G emissions were developed for a range of potential outcomes which attempt to bound actual future year O&G development in the region. CARMMS developed three levels of 2025 future year O&G development within Colorado Planning Areas, the Mancos Shale, and Southern Ute Indian Tribe (SUIT) lands:

- High Development Scenario;
- Low Development Scenario; and
- Medium Development Scenario, which is a mitigated version of the High Development Scenario.

There are four general types of future year emissions addressed in CARMMS:

1. BLM-authorized (Federal lands) and other (non-Federal lands) oil and gas and mining emissions within the Colorado BLM planning areas (as well as the BLM Farmington Field Office in northern New Mexico)

2. Oil and gas and other development areas outside Colorado/northern New Mexico BLM Planning Areas

3. Remainder future year anthropogenic emissions, and

4. Emissions that remained unchanged from the base year in future year scenarios.

3.1 Colorado BLM Planning Area and Mancos Shale Oil and Gas Emissions Calculators

To address emissions from future BLM-authorized (Federal lands) and non-BLM-authorized (non-Federal lands) oil and gas development in Colorado and northern New Mexico planning areas, CARMMS 2.0 has used several emission calculators. For CARMMS 2.0, we developed a new set of emissions calculators for the Royal Gorge Field Office (RGFO) and updated existing emissions calculators for Western Colorado Field Offices for CARMMS 1.0 (ENVIRON et al.; 2015) and the Mancos Shale for CARMMS 1.5 (Ramboll Environ and Kleinfelder, 2016a). The calculators allow the user to readily modify input assumptions, such as production parameters, emission control assumptions, and wellhead equipment configurations. Emissions were developed for O&G activity on SUIT land based on the Supplemental Environmental Impact Statement (SEIS) for Shale Formation Oil and Gas Plan of Development emissions inventory (Ramboll Environ, 2016).

The new and updated emission calculators were used to develop 2025 future-year O&G emissions inventories for (1) eight western Colorado BLM planning areas, (2) four subareas of

the Royal Gorge Field Office Planning Area, and (3) the Mancos Shale in the Tres Rios and Farmington Field Office Planning Areas.

The RGFO is divided into four separate source groups, with three source groups containing mostly conventional oil and gas well development and one source group containing mostly coal bed methane gas well development. One of the conventional oil and gas well areas (RGFO Area 1, see Figure 3-1) is also a non-attainment area for ozone. One of the four RGFO groups covers South Park. Although there are currently no active wells in South Park, CARMMS 2.0 is intended to support the RGFO RMP where there is a Master Leasing Plan (MLP) Alternative for allowing O&G development in South Park.

For the RGFO calculators, we used an emission calculator template similar to the existing calculators developed in CARMMS 1.0 and CARMMS 1.5 for consistency across field offices. Source data used in the RGFO calculators were based on RGFO specific operations and equipment currently in the field. Similarly, the on-the-books regulations used for emission controls also took into account RGFO specific considerations, such as regulations specific to the non-attainment area. The RGFO calculators, for all four of the RGFO source groups, estimate emissions for 2015 to 2025 using current decline curve data and the most recent version of MOVES2014a (Motor Vehicle Emission Simulator version 2014a; EPA, 2015) to create on-road vehicle and off-road equipment emission factors. The RGFO has both conventional oil and conventional gas wells; however, operations at RGFO oil and gas wells are similar so they were combined into one calculator.

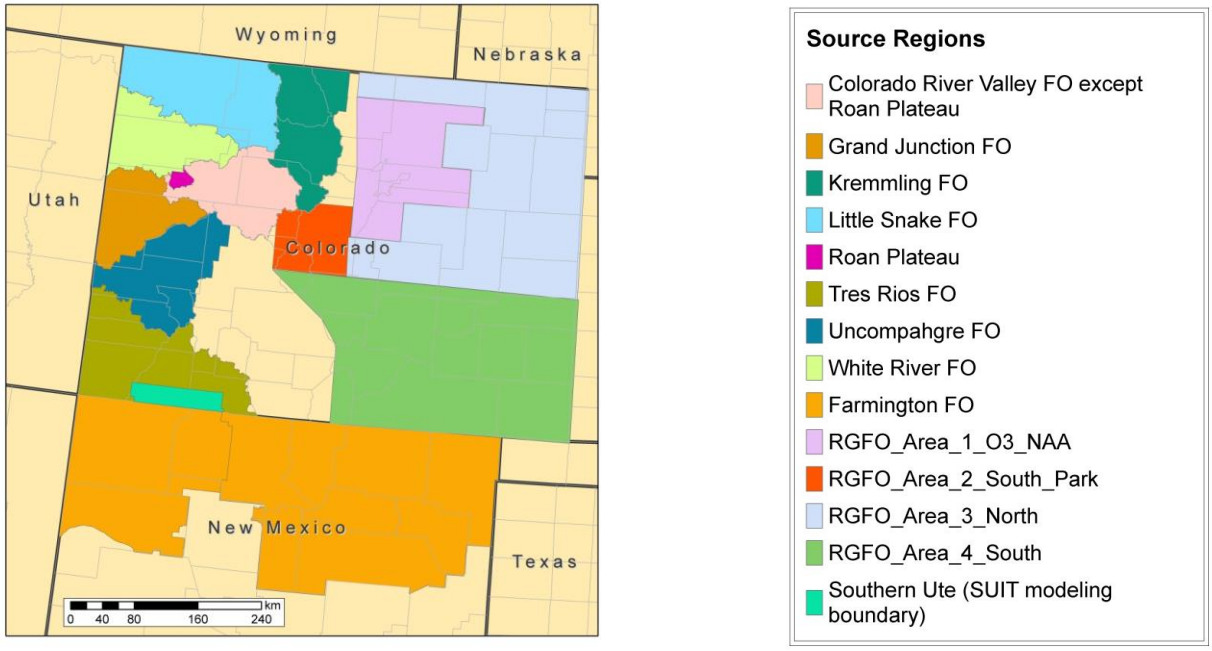

Figure 3-1. Colorado Field Office Planning Areas.

Emission calculator updates for the western Colorado Field Offices and the Mancos Shale include updates to emission controls required by on-the-books regulations, well decline curves, and on-road vehicle and off-road equipment emission factors using the latest version of

MOVES2014a. The Tres Rios Field Office emission calculators were modified to exclude future oil and gas activity on SUIT land because emissions from future oil and gas activity on SUIT land are estimated based on the emissions inventory for the SEIS for Shale Formation Oil and Gas Plan of Development (Ramboll Environ, 2016).

The following sections summarize the emission calculators used to estimate O&G emissions for western Colorado and northern New Mexico. Details on the emission calculators are provided in the Technical Memorandum (Ramboll Environ and Kleinfelder, 2016b), shown in Appendix B.

3.1.1 Overview of Calculators

Emission calculators have been developed for each of the following regions and well types.

- Royal Gorge Field Office
  - Conventional oil and gas
  - Coalbed methane (natural gas) (CBM)
- Western Colorado Field Offices
  - Conventional gas
  - Conventional oil
  - Shale gas
  - Coalbed methane (natural gas) (CBM)
- Mancos Shale
  - Shale gas
  - Shale oil

For each area and well type combination, a separate self-contained emission calculator spreadsheet contains all of the inputs and calculations need to generate well site emissions.

Additionally, a calculator has been developed to estimate midstream emissions for each area. The midstream emission calculator draws upon Colorado Department of Public Health (CDPHE) Air Pollutant Emission Notice (APEN) emissions for base year emission estimates. Future year midstream emission projections are dependent on the change in gas production in a given planning area which can be updated based on linkages to the by well type emission calculators.

3.1.2 Pollutants

The emission calculators include estimates of emissions of criteria air pollutants (CAPs), greenhouse gases (GHGs), and hazardous air pollutants (HAPs) as follows:

Criteria Pollutants

- Carbon monoxide (CO)
- Nitrogen oxides (NO_X)
- Particulate matter less than or equal to 10 microns in diameter (PM_{10})
- Particulate matter less than or equal to 2.5 microns in diameter ($PM_{2.5}$)
- Sulfur dioxide (SO_2)
- Volatile Organic Compounds (VOCs)

Greenhouse Gases[6]

- Carbon dioxide (CO_2)
- Methane (CH_4)
- Nitrous oxide (N_2O)

Hazardous Air Pollutants (HAPs)[7]

While lead (Pb) is a criteria pollutant, emissions of lead in the BLM western Colorado planning areas due to O&G and mining activities are extremely low and are therefore not included in this analysis.

HAP emissions were estimated for each emissions source. For oil and gas emissions sources, HAP emissions from venting and combustion source categories were estimated for formaldehyde, n-hexane, benzene, toluene, ethylbenzene, and xylenes (BTEX).

Anthropogenic greenhouse gas emission inventories typically include carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), and fluorinated gases. Fluorinated gases are not expected to be emitted in appreciable quantities by any category considered in this emission inventory and were therefore not included in this analysis.

The HAP and GHG emissions inventories are provided separately with the CARMMS 2.0 emissions calculators.

3.1.3 Temporal

The calculators estimate annual emissions associated with oil and gas exploration and production. Baseline emissions are estimated for 2015[8] with annual emission forecasts for each year up to 2025. Default temporal profiles available in SMOKE were applied for each source classification code (SCC).

3.1.4 Calculator Inputs

The emission calculator for each well type allows for specification of the following inputs.

- Base year oil and gas activity (gas production, oil production, spud counts, active well counts)
- Well decline estimates
- Level of control by source category
- Gas composition

[6] Note that the CARMMS PGM modeling does not use Greenhouse Gas (GHG) emissions, but the emission calculators provide GHG emission estimates so they can be reported in the RMPs.
[7] Note that the CARMMS PGM modeling does not use HAPs emissions, but the emission calculators provide HAPs emission estimates so they can be reported in the RMPs.
[8] There were several areas (Mancos, RFGO Area 2 and SUIT Land Supplemental Environmental Impact Statement wells) for which there was negligible O&G activity in 2015 and hence zero emissions estimated for 2015. For these areas, emissions were forecast from 2016 (Mancos and RGFO Area 2) or 2018 (SUIT Land Supplemental Environmental Impact Statement wells).

- Equipment configurations (e.g. drill rigs, fracing rigs)
- Gas venting activity (e.g. completions, blowdowns)
- The midstream emission calculator includes estimates of base year 2015 gas plant and compressor station emissions taken from CDPHE APEN data. Base year midstream emissions are forecast to future years based upon the gas production in each planning area.

3.1.5 Emission Calculations

Emission calculations for all emission-generating activities were developed based on typical oil and gas exploration and production emission inventory methodology. Methods used to estimate emissions from each source category are explained in detail in Appendix B. For each source category, emissions for the 2015 baseline were estimated. 2015 baseline emissions are forecasted to future years based on oil and gas activity growth and for applicable sources, emissions controls.

The oil and gas emission estimation methodologies described herein are used consistently in each calculator; however the input data for each calculator was selected to best reflect the operational characteristics of each area and well type combination and thus obtained from literature sources including the following Air Quality Technical Support Documents (AQTSD) from Colorado field office planning areas and BLM emission calculators:

- White River AQTSD (URS, 2012a)
- Colorado River Valley AQTSD (URS, 2012b)
- Grand Junction AQTSD (BLM, 2012b)
- Uncompahgre AQTSD (BLM, 2016c)
- BLM Crude Oil Well Gas Emission Calculator
- BLM Coalbed Natural Gas Well Emission Calculator
- CARMMS information request (BLM 2016a; 2016b)

Emissions are generated in three main phases of oil and gas systems:

- Emissions from Well Construction and Development
- Emissions from the Production Phase (occurring at-or-nearby the well pad)
- Emissions from Midstream Sources (Central Gas Compression and Processing)

The methodologies implemented to estimate base year and future year emissions from oil and gas sources are explained in Appendix B and covered the following source categories:

Well pad construction and development:

- Well pad, access road and pipeline construction equipment;
- Well pad, access road and pipeline construction traffic;
- Drilling and completion equipment;

- Fracing equipment;
- Refracing equipment;
- Drilling and well completion traffic;
- Well pad, access road and pipeline construction wind erosion; and
- Well completion venting.

Production phase emissions:

- Well workover equipment;
- Production traffic;
- Blowdown venting;
- Well recompletion venting;
- Pneumatic devices and fugitive components;
- Water injection pumps;
- Compressor station maintenance traffic exhaust and fugitive dust;
- Condensate or oil tanks flashing and working and breathing losses;
- Loading emissions from condensate and oil tanks;
- Haul trucks traffic emissions;
- Heaters; and
- Dehydrators;

Midstream sources:

- Natural gas processing facilities;
- Natural gas compressor stations; and
- Gas sweetening.

The oil and gas emission calculators are designed to estimate emissions from both BLM-authorized and non-BLM-authorized activities.

3.2 Oil and Gas Emissions outside the Colorado Planning Areas and the Mancos Shale

The following subsections describe the procedures for estimating baseline and future year oil and gas emissions for areas within the CARMMS 2.0 12/4 km modeling domain but outside the Colorado BLM planning areas and the Mancos Shale.

3.2.1 Uinta Basin, Utah

Baseline and future year emissions associated with oil and gas development in the Uinta Basin have been estimated by AECOM for the BLM Utah State Office (UTSO) under the UTSO Air Resource Management Study (ARMS). The UTSO ARMS is using a 2010 baseline year. More details on the oil and gas emissions for the Uinta Basin are available in the UTSO ARMS documentation (AECOM, 2013).

3.2.2 All other O&G basins outside Colorado

Baseline and future year oil and gas emissions for the basins outside Colorado were based on Intermountain West Data Warehouse[9] 2025b inventory.

3.3 Oil and Gas Emissions

The emission calculators were used to generate O&G emissions for the eleven-year period of 2015-2025 for Colorado BLM Planning Areas and the Mancos Shale:

- Royal Gorge Field Office (RGFO)
- Roan Plateau portion of the Colorado River Valley Field Office (CRVFO)
- CRVFO outside the Roan Plateau
- Grand Junction Field Office (GJFO)
- Kremmling Field Office (KFO)
- Little Snake Field Office (LSFO)
- Tres Rios Field Office (TRFO)
- Uncompahgre Field Office (UFO)
- White River Field Office (WRFO)
- Mancos Shale (TRFO, FFO)

For each year from 2015-2025, the emissions calculators were used to estimate O&G emissions for upstream (well site) and midstream emission sources and for O&G development on Federal and non-Federal lands.

Annual 2015-2025 emissions on SUIT land were developed separately from TRFO area emissions for O&G shale activity based on the emissions inventory for the SEIS for Shale Formation Oil and Gas Plan of Development (Ramboll Environ, 2016).

3.3.1 2025 High, Low and Medium Development Scenarios Emissions Overview

The emissions calculators were used to generate O&G emissions within Colorado BLM Planning Areas and the Mancos Shale for 2025 High, Low and Medium Development Scenarios. Oil and gas activity forecasts for BLM Planning Areas in Colorado are based on BLM COSO estimates of RFD O&G future development for the High Development Scenario and historical 5-year average O&G development for the Low Development Scenario. Applicable on-the-books State and Federal controls are applied to the O&G emissions starting in the year that they are required. Mancos Shale oil and gas activity forecasts for the Low Development Scenario and the High Development Scenario remain unchanged from CARMMS1.5. Oil and gas activity forecasts on Southern Ute Indian Tribal land assume 96 spuds and 400 operating wells in 2025 for the High Development Scenario and 48 spuds and 200 active wells in 2025 for the Low Development Scenario. Negligible base year 2015 O&G activity for the Mancos Shale is assumed. Base year emissions on SUIT land are included in TRFO emissions; emissions on SUIT land were distinguished from TRFO emissions only for additional O&G activity resulting from the SEIS for

[9] http://views.cira.colostate.edu/tsdw/

Shale Formation Oil and Gas Plan of Development. All wells drilled as part of the Supplemental Environmental Impact Statement for Shale Formation Oil and Gas Plan of Development are included in this analysis as non-Federal wells.

The Low Development Scenario assumes that in 2025 there are a total of 42,945 active wells in the Royal Gorge Field Office (2% on Federal and 98% on non-Federal land), 27,618 active wells in eight western field offices (51% on Federal and 49% on non-Federal lands), 1,513 active wells in the Mancos Shale (70% on Federal and 30% on non-Federal lands), and 200 active shale wells on SUIT land (all non-Federal). The High Development Scenario assumes that in 2025 there are a total of 55,610 active wells in the Royal Gorge Field Office (4% on Federal and 96% on non-Federal land), 44,018 active wells in eight western field offices (54% on Federal and 46% on non-Federal lands), 3,026 active wells in the Mancos Shale (70% on Federal and 30% on non-Federal lands), and 400 active shale wells on SUIT land (all non-Federal). The 2025 Medium Development Scenario has the same number of wells as the High Development Scenario but assumes additional levels of controls beyond the application of existing state and federal requirements. The Medium Development Scenario assumes additional control of engine and fugitive emission sources for all phases of well-site operation for wells drilled on Federal land and as part of the SUIT land Supplemental Environmental Impact Statement for Shale Formation Oil and Gas Plan of Development after 2015 as shown in Table 3-1.

Table 3-1. Medium scenario additional control assumptions.

Emission Source Category	Medium Scenario Controls
Stationary engines	50% electric engines (50% natural gas-powered)
Pneumatic devices	50% no-bleed (50% low-bleed)
Drilling	Tier 4 gen-set standards for all engines with a horsepower >750; final Tier 4 standards for all engines with horsepower <750
Completion/Fracking	
Blowdowns	25% gas captured and routed to VRUs or flares (75% vented)
Liquids removal system (all produced liquids)	25% taken away by pipeline (75% by truck)
Pneumatic pumps	Unchanged from the High Scenario except in cases where less than 25% of pneumatic pumps emissions are controlled; if less than 25% of pneumatic pumps emissions are controlled then the percentage of pneumatic pumps which are controlled is set to 25%
Unpaved roads dust control	80% fugitive dust control
Construction fugitive dust control	50% fugitive dust control
Condensate Tanks (all produced liquids)	100% of emissions are captured and controlled by VRU or flare
Truck loading emissions	100% of emissions are captured and controlled by VRU or flare
VRUs	50% of emission control devices are assumed to be VRUs (50% flares)

Table 3-2 and Figure 3-2 compare the total 2025 emissions for the Low, Medium, and High Development scenarios across Colorado BLM Planning Areas, SUIT land shale development, and the Mancos Shale. Substantial increases from Low to High Development Scenario emissions result from different O&G activity assumptions (Low and High Development scenarios assume the same level of emissions control). There are substantial decreases in Federal O&G emissions from the High to Medium Development Scenario and smaller decreases from the High to Medium Development Scenario for non-Federal O&G emissions. Differences between the Medium and High Development scenarios are based on increased emissions control for Federal and SUIT O&G shale development in the Medium Development Scenario (activity assumptions are equivalent in the Medium and High Development scenarios). Smaller decreases for non-Federal relative to Federal O&G emissions are because of all non-Federal O&G development, only shale development on SUIT land was assumed to have increased control in the medium scenario.

Table 3-2. Comparison of total oil and gas emissions (tons per year, TPY) across Colorado BLM Planning Areas, SUIT land, and Mancos Shale for 2025 High, Low and Medium Development emission scenarios.

Scenario	VOC	CO	NO_X	PM_{10}	$PM_{2.5}$	SO_2
All Wells						
Low	178,426	107,618	81,136	37,190	7,955	509
Medium	236,734	155,198	125,684	61,621	12,276	1,791
High	251,877	158,478	132,493	66,392	12,977	1,794
Federal Emissions						
Low	26,954	11,814	12,353	2,865	833	308
Medium	43,096	27,785	28,378	4,933	1,692	1,385
High	57,948	30,459	33,919	9,492	2,310	1,387
Non-Federal Emissions						
Low	151,472	95,804	68,783	34,326	7,122	200
Medium	193,638	127,413	97,306	56,688	10,584	406
High	193,929	128,019	98,574	56,900	10,666	407

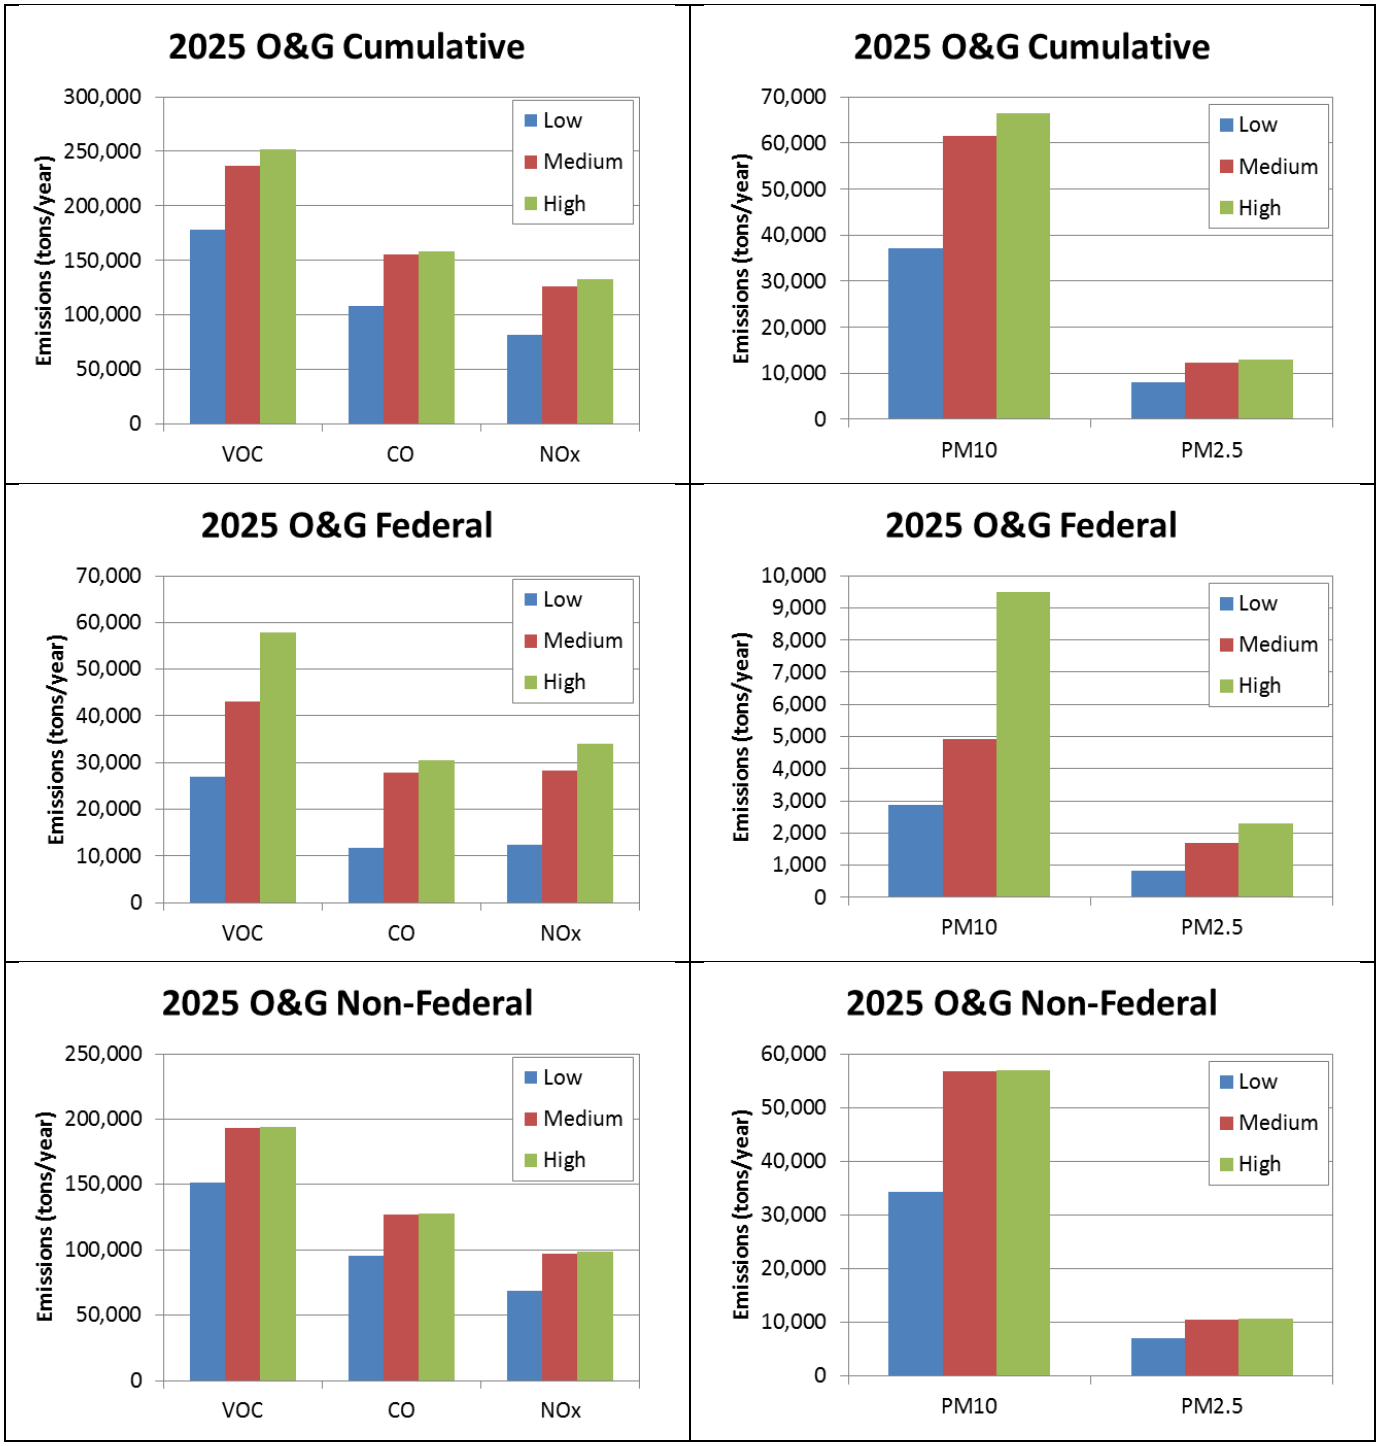

Figure 3-2. Comparison of total oil and gas emissions across Colorado BLM Planning Areas, SUIT land, and Mancos Shale for the 2025 High, Low and Medium Development Scenarios.

As shown in Figure 3-3, increases in 2025 O&G emissions from the Low to Medium Development Scenario are substantial for Federal NOx (130%) and VOC (60%) as well as non-Federal NOx (41%) and VOC (28%) emissions. O&G emission increases from the Medium to the

High Development Scenario are smaller for Federal NOx (20%) and VOC (34%) as well as non-Federal NOx (1%) and VOC (<1%) emissions.

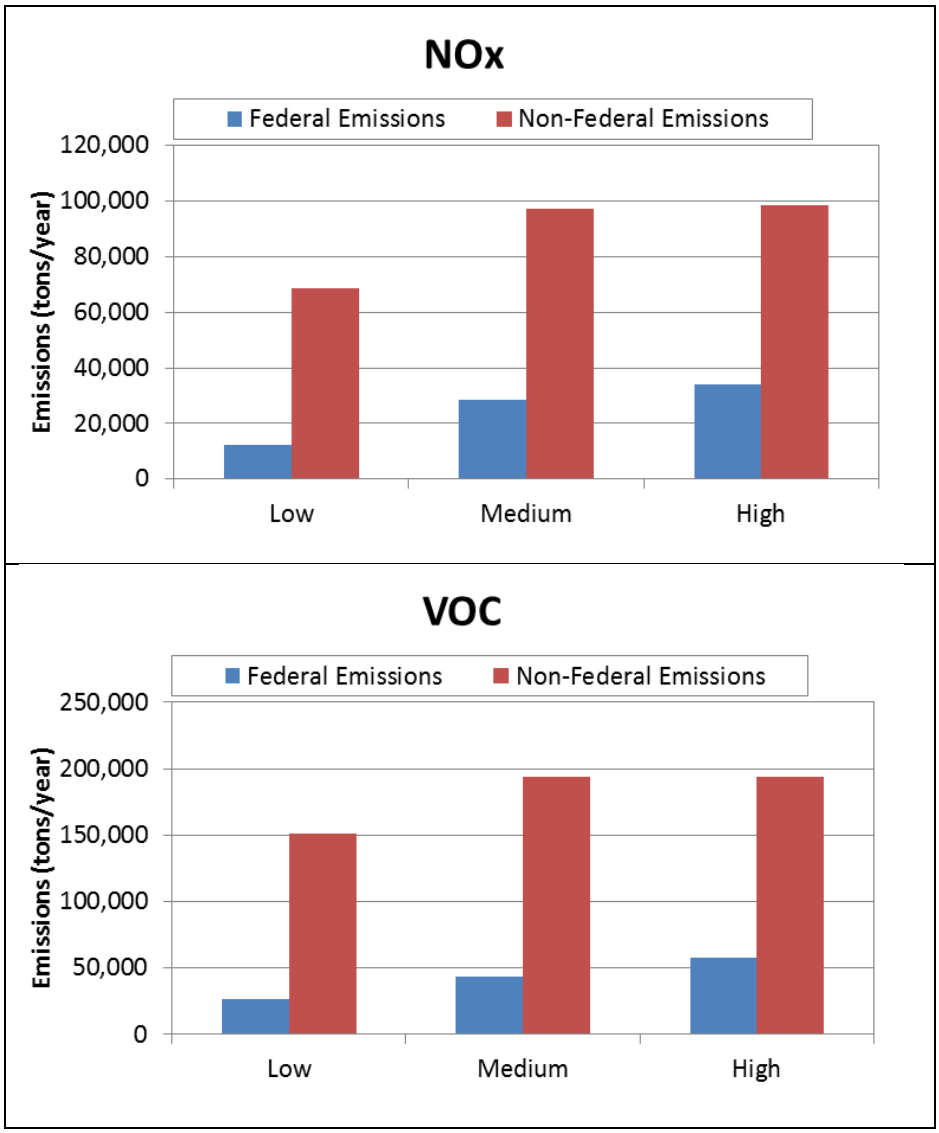

Figure 3-3. By scenario 2025 emissions from oil and gas development across Colorado BLM Planning Areas, SUIT land, and Mancos Shale for NOx (top panel) and VOC (bottom panel).

3.3.2 2025 High, Low and Medium Development Scenarios Emissions

The CARMMS air quality modeling results for the 2025 High, Low and Medium Development Scenarios are presented in Chapter 5. In this section we summarize the emissions for the Colorado BLM Planning Areas, SUIT land shale development, and Mancos Shale by scenario for 2025 emission scenarios. Table 3-3 displays NO_X and VOC O&G 2015 and 2025 emissions (and percent change 2015 to 2025) by planning area for each scenario stratified by Federal and non-Federal lands. We note that the first year of O&G activity for the Mancos and RGFO Area 2 emissions is 2016 and for the SUIT Supplemental EIS for Shale Formation Oil and Gas Plan of Development is 2018. Emissions are estimated to be negligible from Mancos, RGFO Area 2, and

SUIT in 2015. We also note that the 2025 emissions include new emissions and some existing emissions that have declined. Summary spreadsheets (not shown here) also include emissions stratified by upstream versus midstream, provide emissions per well, and all associated well-site equipment input factors and O&G activity assumptions. Generally, medium scenario federal emission magnitudes are smaller than the high scenario and greater than the low scenario federal emissions for each field office. The exception is medium scenario NOx emissions from O&G shale development on SUIT land which are smaller than low scenario emissions as a result of the application of medium scenario control assumptions to the SEIS for Shale Formation Oil and Gas Plan of Development emissions inventory (Ramboll Environ, 2016).

Table 3-3. Summary of oil and gas NO_X and VOC emissions within the Colorado BLM Planning Areas, SUIT land, and Mancos Shale for the 2015 current year and 2025 High Development Scenarios (2025 emissions include both existing and new O&G sources).

2015	NO_X Emissions (TPY)			VOC Emissions (TPY)		
BLM Area	**Federal**	**non-Fed**	**Total**	**Federal**	**non-Fed**	**Total**
RGFO - Area 1	449	36,731	37,180	1,618	84,277	85,894
RGFO - Area 2	0	0	0	0	0	0
RGFO - Area 3	406	8,589	8,996	3,730	41,194	44,924
RGFO - Area 4	100	3,743	3,843	286	5,060	5,346
CRVFO (No Roan)	1,960	1,748	3,708	7,251	6,532	13,782
Roan (CRVFO)	1,734	936	2,670	2,890	1,620	4,509

Figure 3-4 shows the wide range of emissions splits by Federal and non-Federal well types for each planning area. RGFO Area 1 and SUIT have the highest percent of emissions from non-Federal O&G activity and WRFO has the highest percent of emissions from Federal O&G activity.

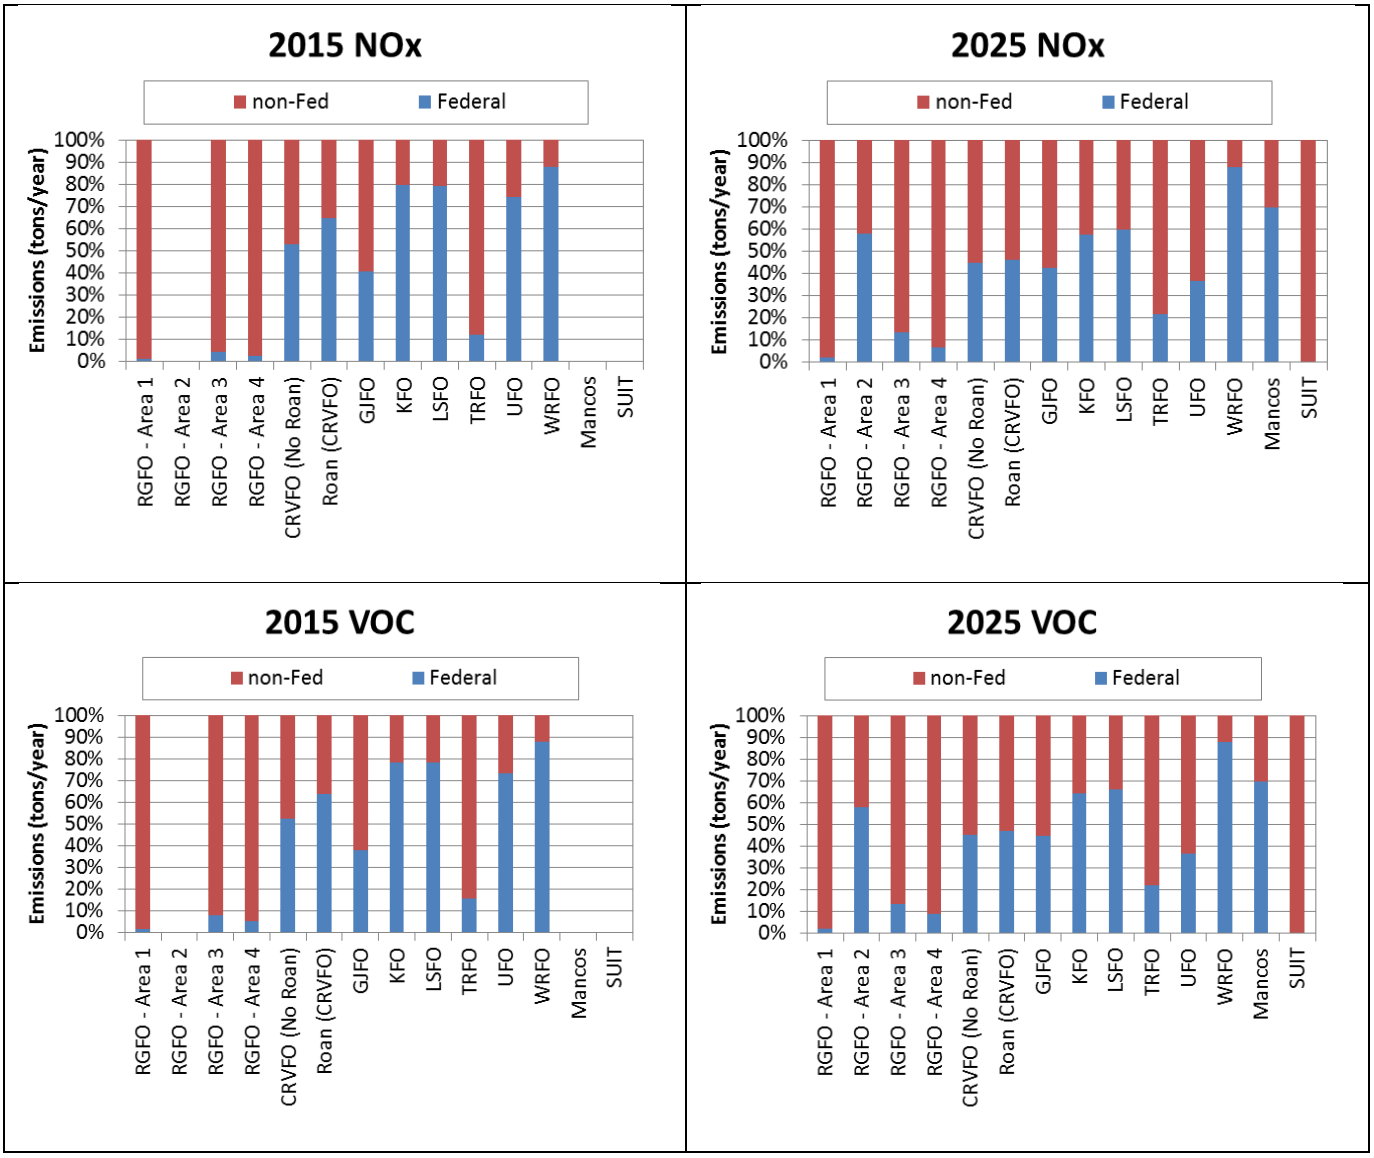

Figure 3-4. NO_X and VOC emission contributions from O&G development by planning area for the 2015 current (left) and 2025 High Development Scenario (right) emissions scenarios.

3.4 Other Anthropogenic Emissions

Other anthropogenic emissions (i.e., non O&G and BLM authorized mining sources) for the 2025 future year were taken from IWDW-WAQS 2025 Future Year Platform (see Section 3.6.2 for details).

3.5 Emissions that Remain at 2011 Levels

The following emission categories from the 2011 Base Case emissions scenario (see Section 2.3) were assumed to remain unchanged for the 2025 future year emission scenarios:

- Biogenic emissions;
- Wildfires, Prescribed Burns and Agricultural Burning emissions;
- Lightning emissions;
- Sea Salt emissions;
- Windblown Dust emissions.

3.6 Future Year Emissions Modeling

3.6.1 Future Year Emissions Modeling Procedures

The 2025 future year emissions were processed using the SMOKE emissions model and each source category for which separate ozone and particulate matter contributions are needed was processed in a separate stream in the SMOKE emissions modeling. This resulted in many different streams of SMOKE emissions processing for the three 2025 emission scenarios to provide separate source groups so that the AQ/AQRV impacts can be isolated in the source apportionment modeling.

3.6.2 Non-Oil and Gas Future-Year Emissions Data

The 2025 inventory and ancillary emissions data for some of the inventory sectors were obtained directly from the WAQS IWDW year 2025 modeling platform, which in turn uses data from EPA's 2011v6.2 modeling platform. A summary of the 2025 WAQS (IWDW) modeling platform inventory is provided below and additional details are available from IWDW website[10] and EPA's Technical Support Document for the 2011v6.2 platform[11].

CEM Point: For Electric Generating Units (EGUs) with Continuous Emissions Monitors (CEMs), EPA developed the 2025 EGU-specific emissions based on the Integrated Planning Model (IPM®[12]) version 5.14 including controls from the Cross-State Air Pollution Rule (CSAPR), the Final Mercury and Air Toxics (MATS), Regional Haze Rule, and Cooling Water Intakes Rule. Revised 2025 EGU emissions for Colorado with updates on retirement/conversion of EGUs that are not accounted for in the 2025 EPA projections were obtained from the Colorado Department of Public Health and Environment (CDPHE) and implemented in SMOKE processing.

[10] http://vibe.cira.colostate.edu/wiki/wiki/7112/waqs-2011b-platform-future-year-emissions
[11] https://www.epa.gov/sites/production/files/2015-10/documents/2011v6_2_2017_2025_emismod_tsd_aug2015.pdf
[12] https://www.epa.gov/airmarkets/power-sector-modeling

EGUs within Colorado and New Mexico were separated into coal and oil/gas EGUs in SMOKE processing to address the indirect effects of coal and oil/gas EGU projects.

Non-CEM Point: Projection factors and percent reductions reflect emissions reductions due to national and local rules, control programs, plant closures, consent decrees and settlement. Annual Energy Outlook (AEO) fuel volume projections were used for projections for corn ethanol and biodiesel plants. Terminal area forecast (TAF) data were used for aircraft for projection in landing/takeoff activity.

Nonpoint/Area: Agricultural sector projection factors for livestock estimates based on expected changes in animal population from 2005 Department of Agriculture data, updated based on personal communication with EPA experts in July 2012. Fugitive dust projection factors for dust categories related to livestock estimates based on expected changes in animal population and AEO-based vehicle miles travelled (VMT) growth for paved and unpaved roads. Residential wood combustion projections based on growth in lower-emitting stoves and a reduction in higher emitting stoves. Portable Fuel Container (PFC) projection factors reflecting impact of the final Mobile Source Air Toxics (MSAT 2) rule and the Renewable Fuel Standard (RFS2). Upstream impacts from AEO fuel volume, including cellulosic ethanol plants are also reflected.

Off-road Mobile: Other than for California and Texas, this sector uses data from a run of NMIM that utilized NONROAD2008a, using future-year equipment population estimates and control programs to the year 2025 and using national level inputs. Final controls from the final locomotive-marine and small spark ignition rules are included. California and Texas-specific data were provided by California Air Resources Board (CARB) and Texas Commission on Environmental Quality (TCEQ), respectively.

Aircraft/locomotive/marine: Projection factors for Category 1 and Category 2 commercial marine and locomotives reflect final locomotive-marine controls.

Offshore shipping: Base-year 2011 emissions grown and controlled to 2025, incorporating controls based on Emissions Control Area (ECA) and International Marine Organization (IMO) global NO_X and SO_2 controls.

On-road Mobile, not including refueling: MOVES2014-based emissions factors for year 2025 were developed using the same representative counties, state-supplied data, meteorology, and procedures that were used to produce the 2011 emission factors. California-specific data were provided by CARB. Other than California, this sector includes all non-refueling on-road mobile emissions (exhaust, evaporative, evaporative permeation, brake wear and tire wear modes).

On-road Refueling: Uses the same projection and processing approach as the on-road sector with an additional step that replaced gasoline refuelling estimates with Colorado submitted point emissions for some counties.

Natural Emissions: Biogenic, wildfires, prescribed burns, agricultural burning, lightning, and wind-blown dust emissions are held constant at 2011 levels.

We note that the cumulative effect of emissions from downstream combustion of oil and gas extracted in Colorado is accounted in one or more of the emissions sectors described above. In addition, the cumulative effect of combustion occurring outside the modeling domain is represented through the boundary conditions.

Most of the ancillary data (spatial/temporal/chemical) were held unchanged from the WAQS 2025 modeling platform, which were taken directly from the EPA 2011v6.2 modeling platform. The pre-merged emissions files for sectors listed above were obtained from WAQS 2025 modeling platform and "windowed" to prepare CAMx-ready emissions for the CARMMS 2.0 12/4km domain for year 2025 modeling.

3.6.3 Oil and Gas Future-Year Emissions Data

Emissions inventories for oil and gas sources in Colorado were prepared as described in Section 3.1. For oil and gas sources within the BLM planning areas, emissions were divided into existing and RFD (new) source categories to facilitate CAMx source apportionment processing. The RFD sources were further divided into oil and gas development on the BLM-authorized (Federal) and other (non-Federal) lands. For the Southern Ute Indian Tribe (SUIT) emissions for year 2025, we leveraged the inventory/calculator developed for the programmatic SUIT SEIS by Ramboll Environ (2016).

For processing oil and gas emissions, we developed ancillary data (spatial/temporal/chemical) specific to planning areas. The area-specific spatial allocation profiles were developed from the data provided by BLM and chemical speciation profiles were prepared from the gas composition available in the emission calculator. Table 3-4 provides a list of speciation and gridding profiles developed by planning areas. The conventional (CG) and CBM gas speciation profile are assigned to source categories associated with the respective well type.

Table 3-4. Source of VOC speciation profile and spatial surrogates used for gridding oil and gas emissions in the federal planning areas in Colorado.

Source Region	Speciation Profiles	Gridding Profiles
Colorado River Valley, without Roan	CRV{CG}	CRVFO {CG}{Fed,non-Fed}
Grand Junction FO	GJ {CBM,CG,SG}	GJFO {CG,CBM}{Fed,non-Fed}
Kremmling FO	K {CBM,CG,CO}	KFO shapefile
Little Snake FO	LS {CG,CO}	CRVFO {CG}{Fed,non-Fed}
Roan Plateau	CRV{CG}	CRVFO_Roan_Plateau.
Tres Rios FO	TR {CBM,CG,CO,SHL}	TRFO {CG,CBM}{Fed,non-Fed}
Uncompahgre FO	U {CBM,CG}	UFO {CG,CBM}{Fed,non-Fed}
White River FO	WR {CG,CO}	WRVFO {CG}{Fed,non-Fed}
Pawnee National Grasslands	DJ{FLA ,VNT}	RGFO {CG}{Fed}
Royal Gorge FO Area1	DJ{FLA ,VNT}	RGFO {CG}{Fed,non-Fed}
Royal Gorge FO Area2	DJ{FLA ,VNT}	RGFO {CG}{Fed,non-Fed}
Royal Gorge FO Area3	DJ{FLA ,VNT}	RGFO {CG}{Fed,non-Fed}
Royal Gorge FO Area4	DJ{FLA ,VNT}	RGFO {CG}{Fed,non-Fed}

For spatial allocation, gridding profiles were developed for each well type (i.e., conventional, CBM) and land type (Federal, non-Federal) combination.

3.6.4 Mining Future-Year Emissions Data

For mining sources, emissions were estimated for coal and uranium mines on Federal lands in the western Colorado BLM Planning Areas. The emissions for mines on Federal lands were estimated based on the CDPHE APEN database and available EISs and EAs. The mining emissions not on federal lands were obtained from the 2025 EPA/WAQS inventory. EPA default chemical speciation profiles were used in the SMOKE emissions modeling for mining except that the EPA mining $PM_{2.5}$ speciation profile was adjusted as described in Section 3.7.1 of the CARMMS1.5 report.

The estimated coal mining sources were consolidated with the 2025 EPA/WAQS inventory to avoid potential double counting and modeled as "point". The western Colorado uranium mining emissions were modeled as "area" and spatially allocated using spatial surrogates developed from the data provided by BLM in a shapefile format.

3.7 Emissions Modeling Results

The CARMMS 2.0 CAMx source apportionment modeling used 23 emission source categories plus three combined O&G source groups as well as total anthropogenic and all emissions within the 12/4 km CARMMS 2.0 domain (see Section 4).

Table 3-5 lists the total NO_X, VOC, SO_2 and $PM_{2.5}$ and PM_{10} emissions for these source categories/groups as applied in the CARMMS 2.0 2025 High Development Scenario source apportionment simulation. These emissions were obtained from the SMOKE scenario reports created by the Smkreport processor for each day of the annual simulation and summed to obtain total annual emissions.

When considering new Federal O&G within the 14 BLM Planning Areas and the 2025 High Development Scenario (Table 3-5), the WRFO has the highest NO_X emissions (10,185 tons per year, TPY) followed by GJFO (4,703 TPY), FFO (3,184 TPY) and SUIT (2,383 TPY). Total 2025 O&G NO_X emissions in the 14 BLM Planning Areas is 132,491 TPY that is split into 22 percent new Federal (29,281 TPY), 35 percent new non-Federal (46,443 TPY) and 43 percent existing O&G emissions (56,767 TPY). Outside the 14 BLM Planning Areas, there is an additional 149,661 TPY O&G NO_X emissions for a total 2025 High Development Scenario O&G NO_X emissions across the entire 4 km CARMMS domain of 282,152 TPY that represents 38 percent of the total anthropogenic and 31 percent of the total (anthropogenic plus natural) NO_X emissions in the 4 km domain.

Total O&G VOC emissions in the 4 km CARMMS domain for the 2025 High Development Scenario are 633,801 TPY that represents 70 percent of the total anthropogenic and 21 percent of the total anthropogenic plus natural VOC emissions across the domain. Natural VOC emissions represent 70 percent of the annual VOC emissions across the 4 km CARMMS domain. Note that biogenic emissions are highly day-specific with higher emissions under warmer

temperatures and higher light intensity. Thus, the contributions of biogenic VOC emissions to the total annual VOC emissions (70 percent) would be expected to be lower on cooler and higher on warmer days. Also note that the VOC emissions in Table 3-5 were obtained from the Carbon Bond chemical mechanism species that will be different than the VOC species input into the SMOKE emissions modeling system (for example, includes ethane and excludes nonreactive carbon in VOCs).

With one exception, SO_2 emissions from Federal O&G within the 14 BLM Planning Areas are fairly low (< 20 TPY). The exception is the WRFO Planning Area where the 1,173 TPY SO_2 emissions represent 95 percent of the 1,240 TPY SO_2 emissions from all 14 BLM Planning Areas combined in the 2025 High Development Scenario. A majority of the 2025 SO_2 emissions in the WRFO Planning Area come from two gas plants: the Enterprise Gas Proc – Meeker Gas Plant and the Williams Field – Willow Creek Gas Plant. These gas plant emissions were based on the CDPHE 2008 Air Pollution Emission Notice (APEN) database grown to 2025 using the change in gas production between 2008 and 2025 for the 2025 High, Low and Medium Development Scenarios. Total O&G SO_2 emissions across the CARMMS domain is 6,960 TPY that is primarily (74 percent) due to O&G from outside the 14 BLM Planning Areas, these areas in the 4 km CARMMS domain outside the 14 BLM Planning Areas includes the Uinta Basin where sour gas reserves occur.

Total $PM_{2.5}$ emissions from O&G in the 14 BLM Planning Areas and the 2025 High Development Scenario is 12,977 TPY of which 16 percent is due to new Federal O&G and the rest approximately split equally between new non-Federal and existing O&G. Mining within the 14 BLM Planning Areas contributes 1,148 TPY. By far the largest contribution of primary $PM_{2.5}$ emissions is the other (non O&G and mining) anthropogenic emissions category that contributes 59 percent of the region-wide total with natural emissions (mostly due to wildfires) contributing most of the rest (37 percent).

Table 3-6 and Table 3-7 are like Table 3-5 but for the 2025 Low and Medium Development Scenario, respectively. The three scenarios only differ in emissions from the new O&G and mining activities from the 14 BLM planning areas; emissions from other source categories do not vary across scenarios.

With the revisions made to the Mancos Shale Low Development Scenario inventory in the current study (CARMMS 2.0), the 2025 emissions from new Federal sources in the FFO are 50% (data not shown here) lower than in the High Development Scenario for all pollutants. The total new Federal O&G NO_X emissions across the 14 BLM Planning Areas for the low scenario (6,649 TPY) are 77% lower than the high scenario (29,281 TPY). Similar reductions are seen for the other species (-76 to -87 percent). Note that for the 2025 Low Development Scenario, there are no emissions from RGFO #2. The annual emissions for the 2025 Medium Development Scenario are shown in Table 3-7. Total O&G NO_X emissions across the 14 BLM Planning Areas for the 2025 Medium Development Scenario are 22,138 TPY that is 24% (data not shown here) lower than the 2025 High Development Scenario. Similarly, 2025 Medium Development Scenario O&G VOC emissions across the 14 BLM Planning Areas are 37% lower than the 2025 High Development Scenario.

Table 3-5. Total emissions (tons per year) for each Source Category and combinations of Source Categories for the 2025 High Development Scenario from the SMOKE scenario reports.

Figure 3-5 to Figure 3-11 displays spatial maps of NO_X, VOC and $PM_{2.5}$ emissions across the 4 km CARMMS domain by different source types for the 2025 High, Medium and Low Development Scenarios. The spatial maps for the Medium and Low Development Scenarios have the same locations as the High Development Scenario just with lower intensity. Figure 3-5 displays the total new Federal O&G emissions across the Colorado BLM Planning Areas and Figure 3-6 shows the total new non-Federal O&G emissions across all the 14 BLM Planning Areas. Most of the new Federal O&G emissions are located in the western Colorado Planning Areas (e.g. Roan Plateau and the surrounding areas) while the new non-Federal O&G emissions are mainly located in the eastern Colorado Planning Areas (e.g. RGFO #1).

Figure 3-7 and Figure 3-8 displays the spatial distribution of NO_x, VOC and $PM_{2.5}$ emissions from existing O&G activities within and outside the 14 CO/NM BLM Planning Areas, respectively, which do not vary across different scenarios. In addition to the familiar Basins within the 14 CO/NM Planning Areas (Denver-Julesburg, Piceance and North and South San Juan), the Uinta Basin is clearly evident along with O&G emissions in eastern Utah. Spatial distribution of mining

emissions within the BLM Planning Areas is shown in Figure 3-9, which consists of mainly isolated grid cells. Figure 3-10 and Figure 3-11 displays the other (remainder) anthropogenic emissions and natural emissions, respectively. Roadways and the major urban areas of Denver, Salt Lake City, Colorado Springs and Albuquerque are clearly evident in the other anthropogenic emissions NO_X and VOC maps. Whereas the spatial maps of other anthropogenic $PM_{2.5}$ emissions is more reflective of agricultural sources. Natural VOC emissions are dominated by forested areas, whereas the natural NO_X emissions are higher in agricultural areas and the locations of fires in 2011[13]. For example, the Las Conchas Fire started in Santa Fe National Forest on June 26, 2011, resulted in substantial emissions in Los Alamos County.

[13] https://en.wikipedia.org/wiki/Las_Conchas_Fire

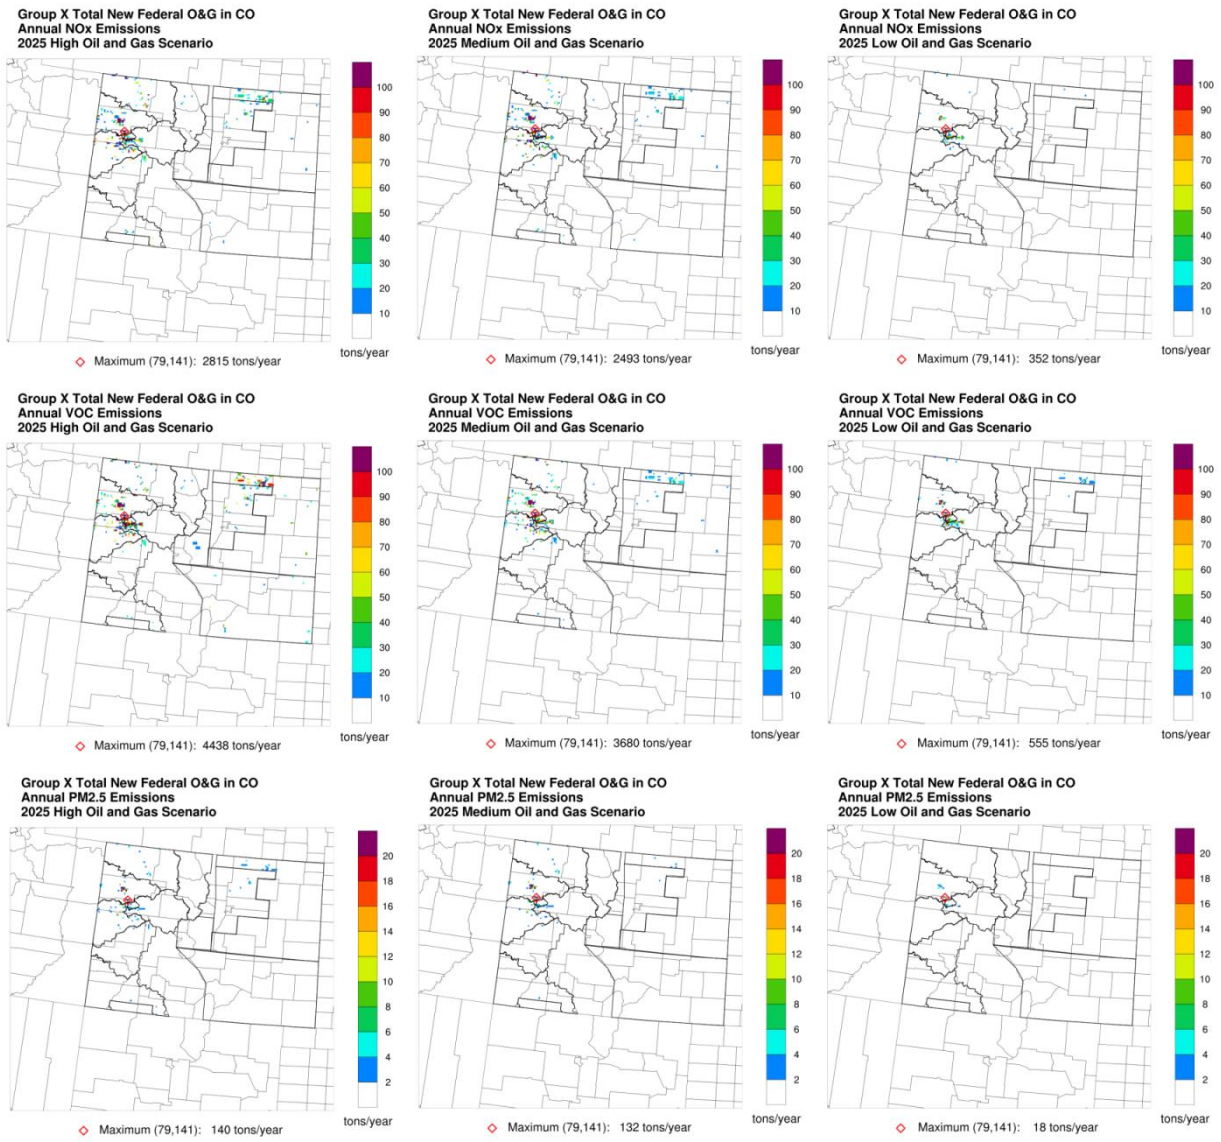

Figure 3-5. Spatial distribution of total new Federal oil and gas NOX (top row), VOC (middle row) and PM2.5 (bottom row) emissions (tons per year) for the 14 BLM Planning Areas in the 2025 High (left column), Medium (middle column) and Low (right column) Development Scenario.

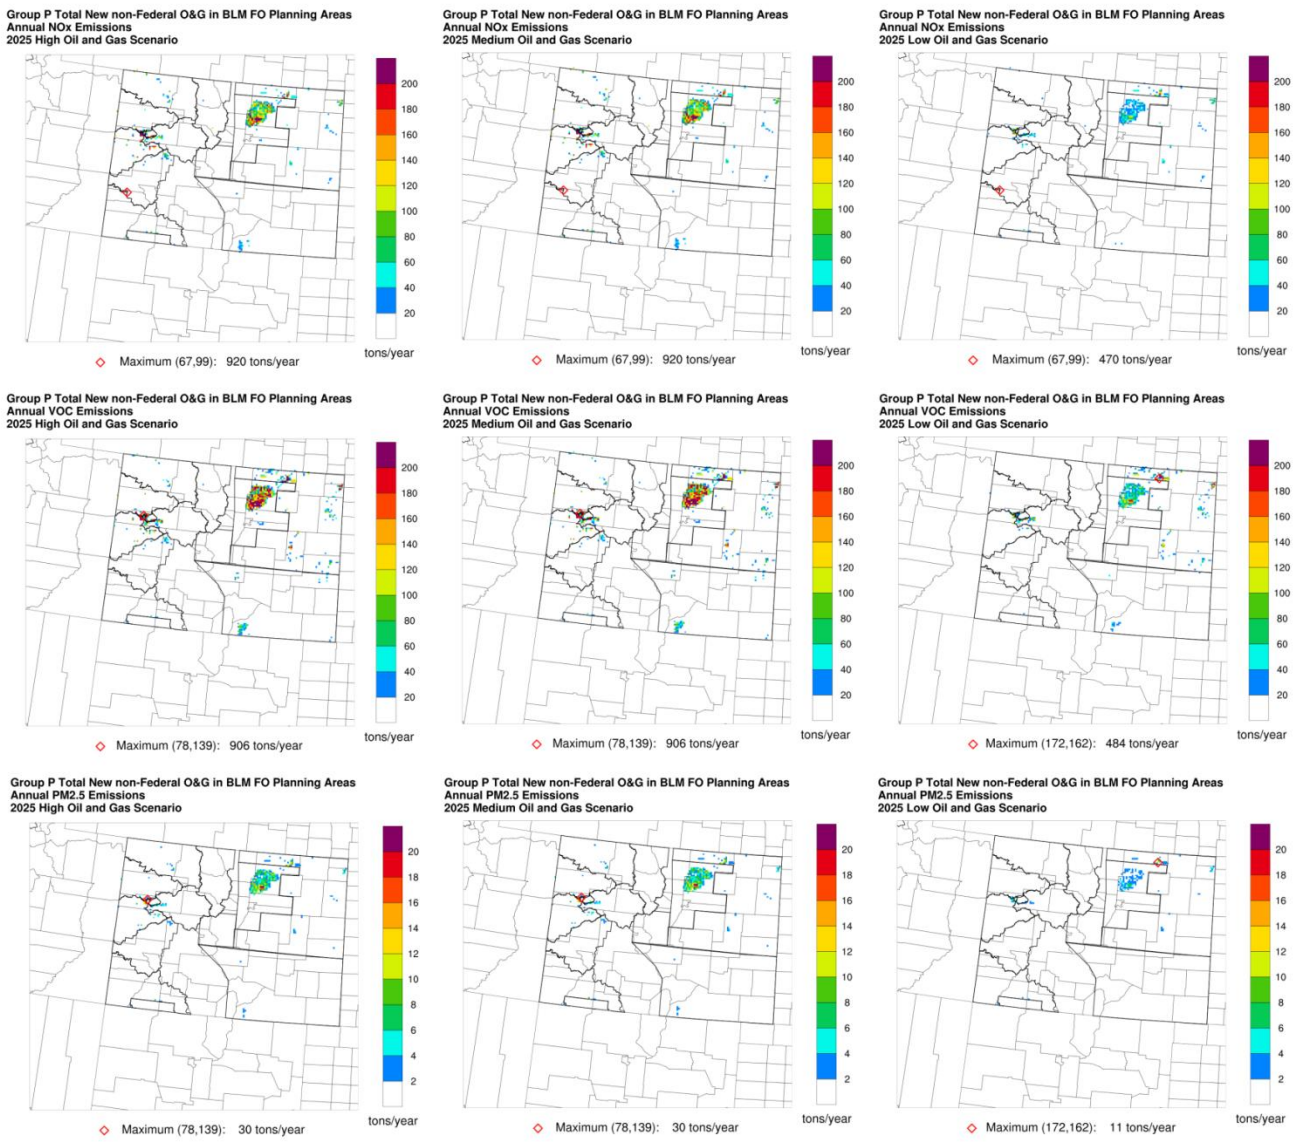

Figure 3-6. Spatial distribution of total new non-Federal oil and gas NOX (top row), VOC (middle row) and PM2.5 (bottom row) emissions (tons per year) for the BLM Planning Areas in the 2025 High (left column), Medium (middle column) and Low (right column) Development Scenario.

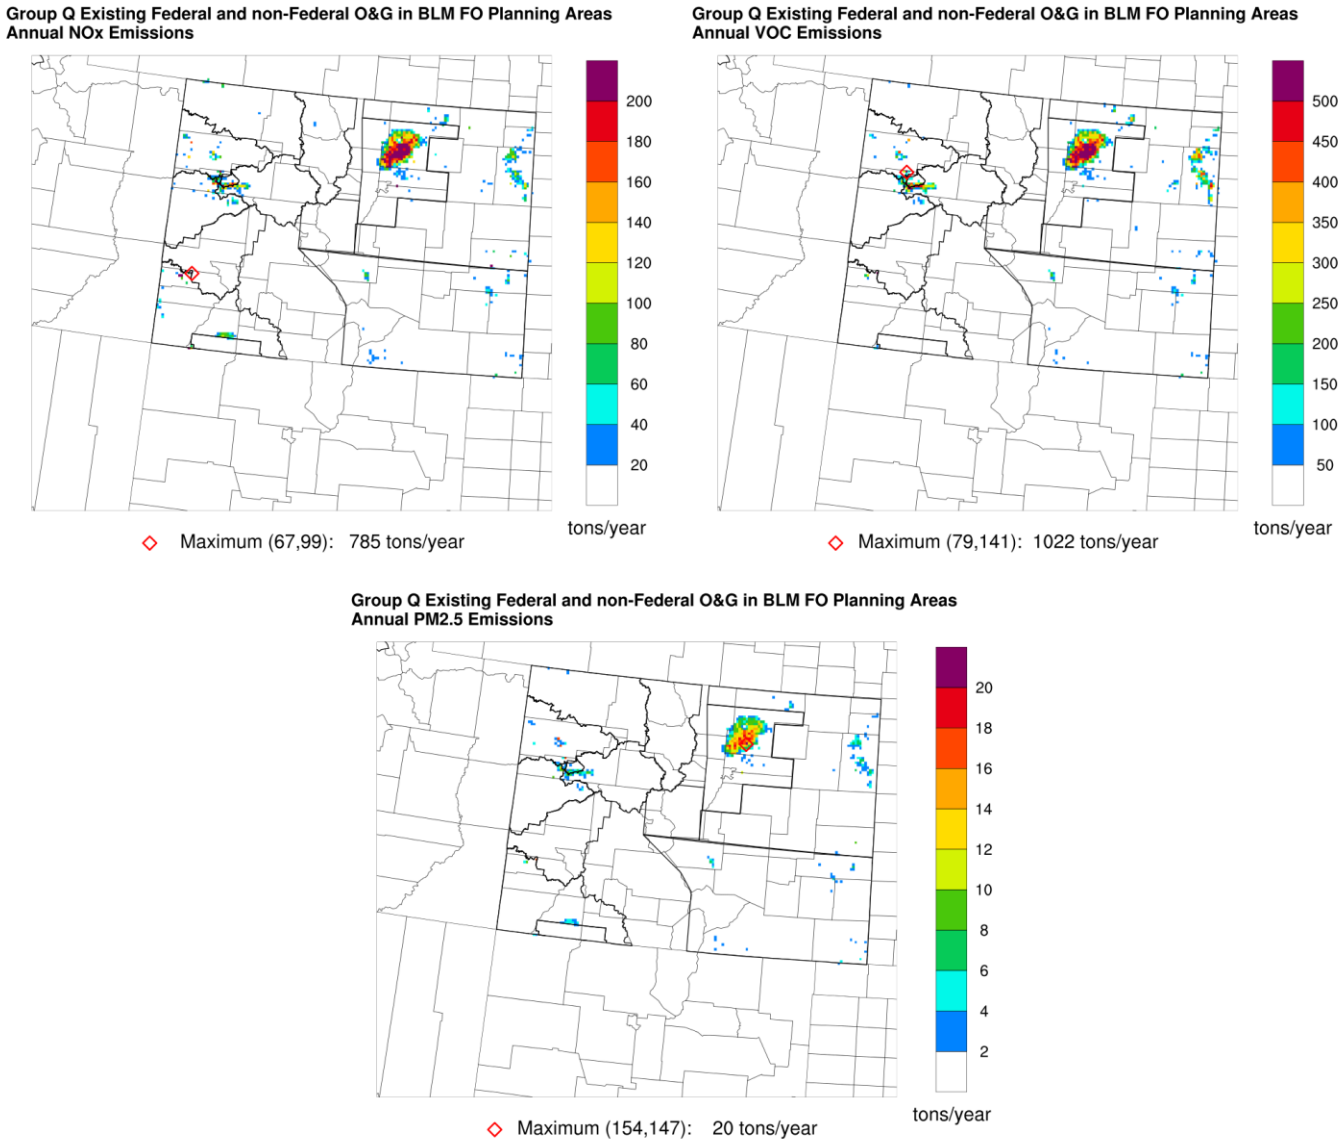

Figure 3-7. Spatial distribution of existing Federal and non-Federal oil and gas NOX (top left), VOC (top right) and PM2.5 (bottom) emissions (tons per year) for the BLM Planning Areas.

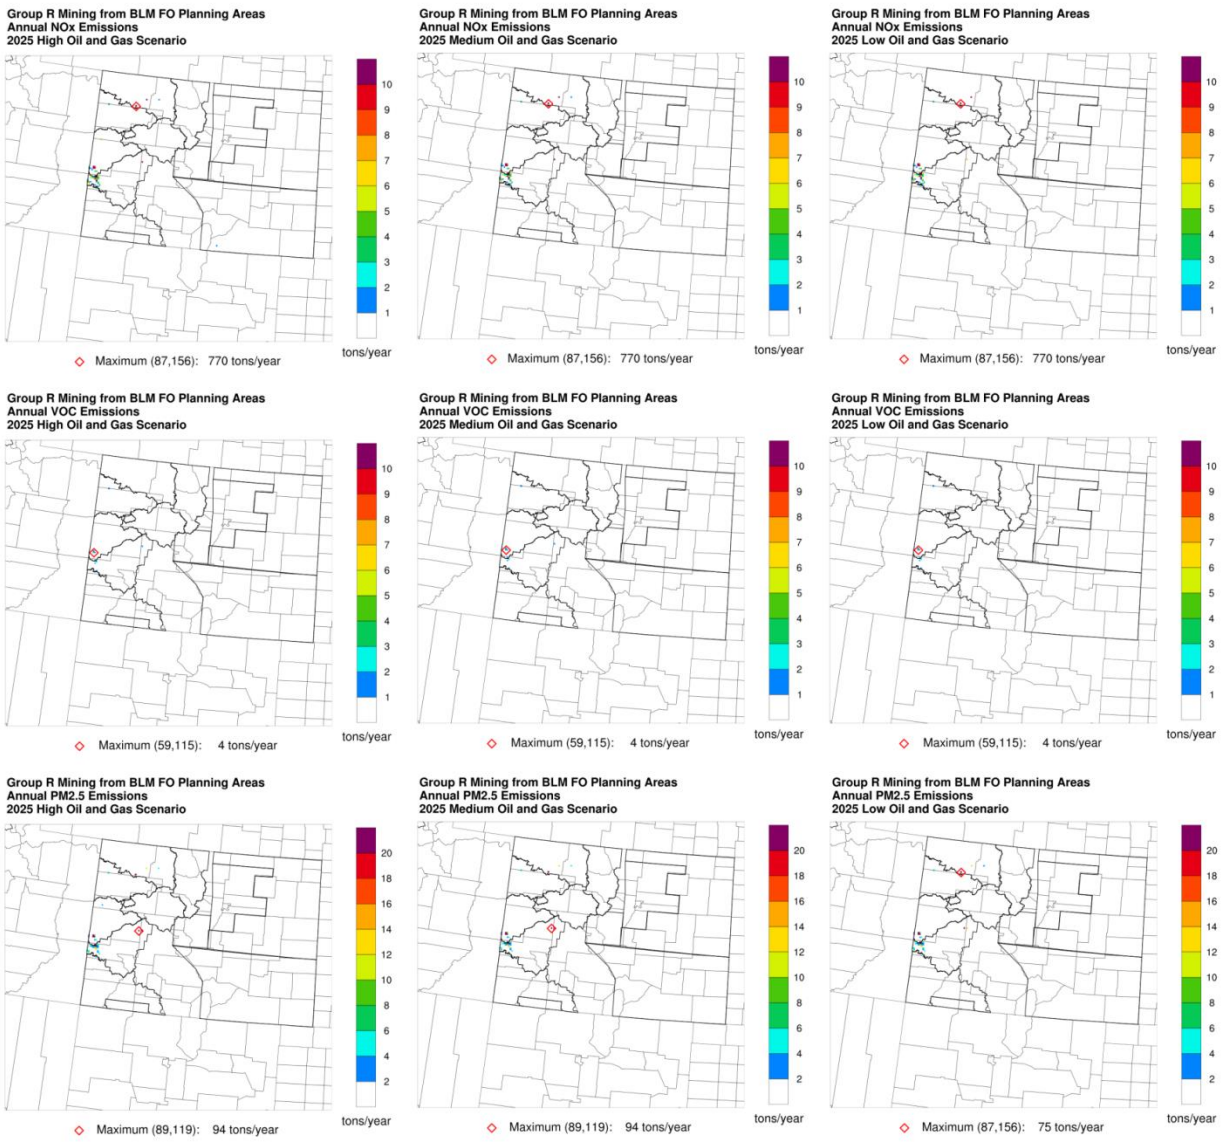

Figure 3-9. Spatial distribution of mining NOX (top row), VOC (middle row) and $PM_{2.5}$ (bottom row) emissions (tons per year) for the BLM Planning Areas in the 2025 High (left column), Medium (middle column) and Low (right column) Development Scenario.

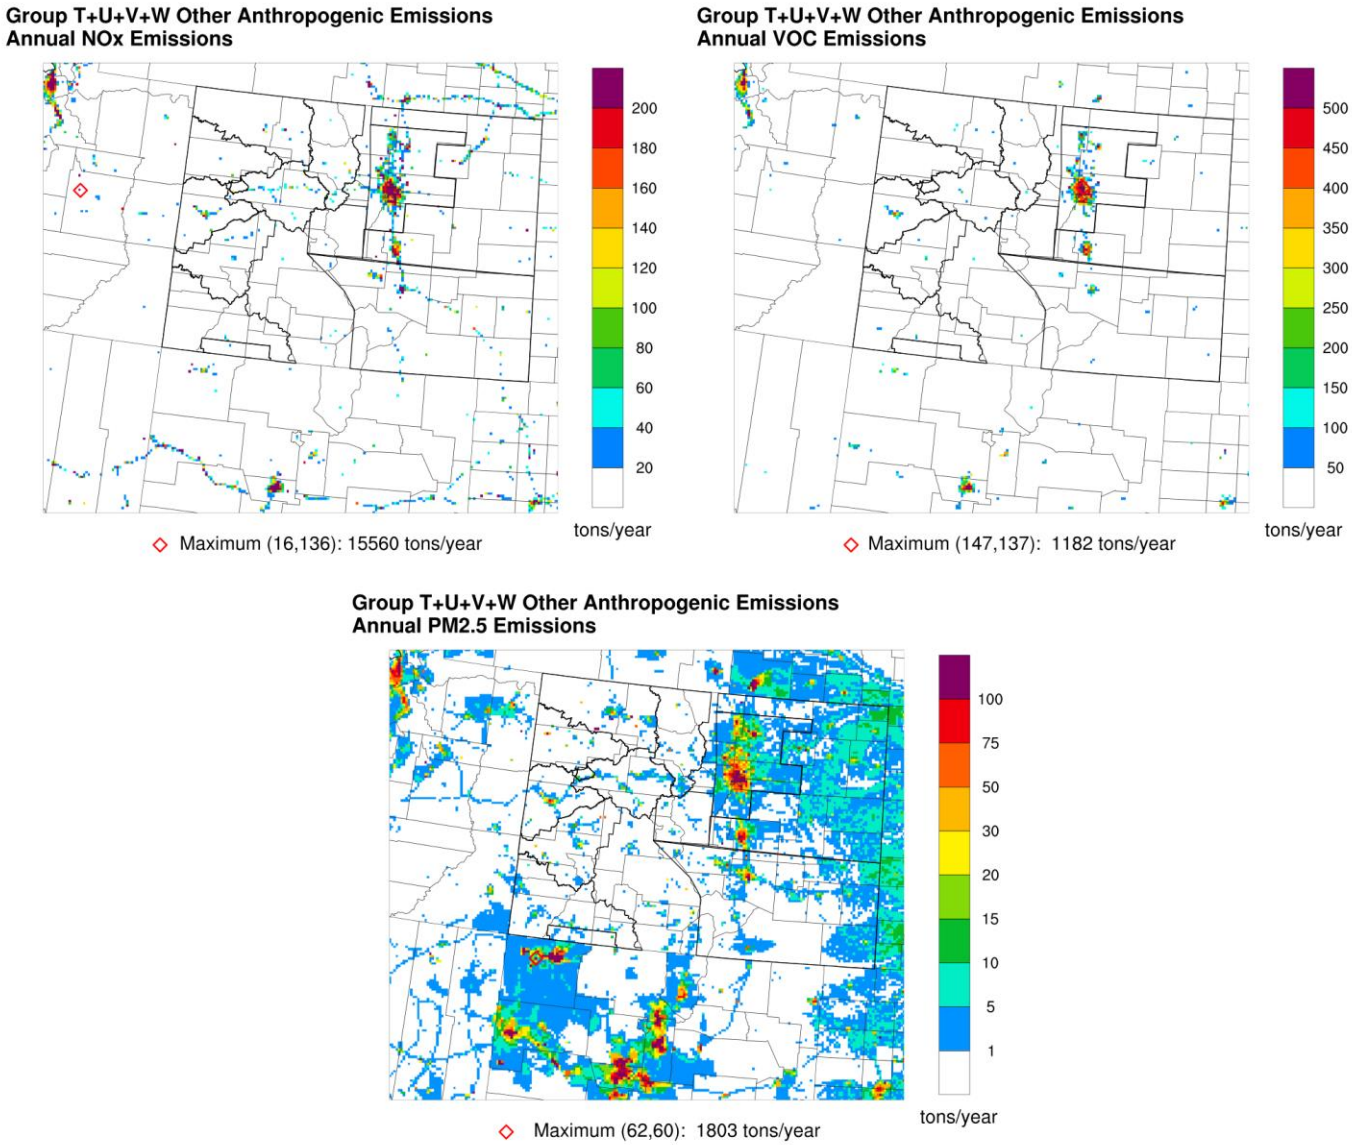

Figure 3-10. Spatial distribution of other anthropogenic NOX (top left), VOC (top right) and $PM_{2.5}$ (bottom) emissions (tons per year) for the CARMMS 4km domain.

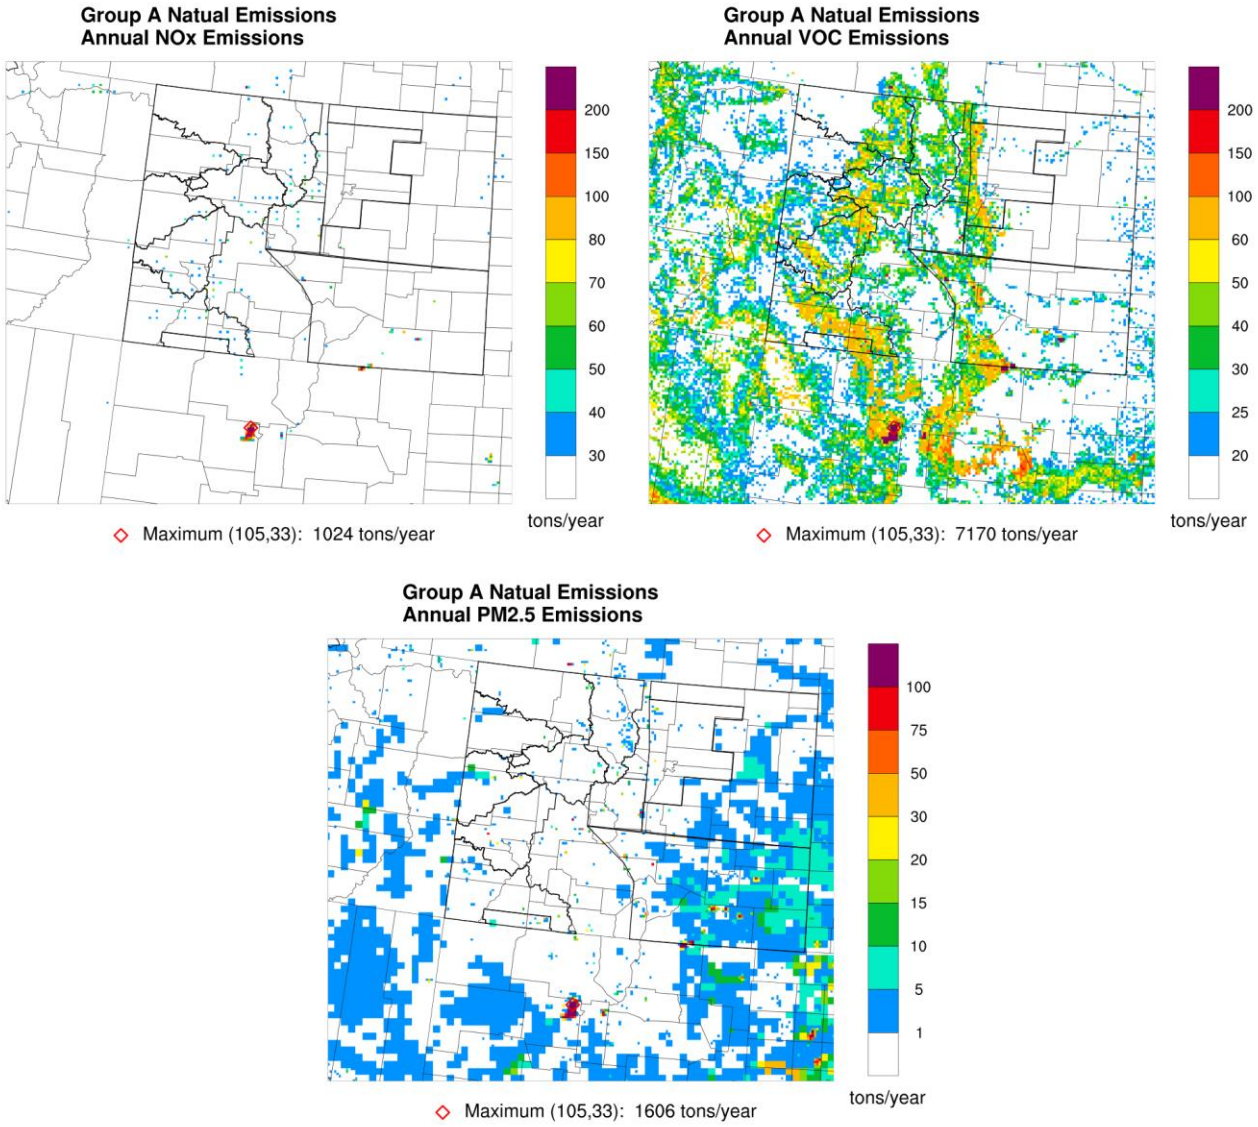

Figure 3-11. Spatial distribution of natural NOX (top left), VOC (top right) and $PM_{2.5}$ (bottom) emissions (tons per year) for the CARMMS 4km domain.

4.0 FUTURE YEAR MODELING AND ANALYSIS APPROACH

The CAMx source apportionment tool was used to obtain separate contributions of BLM authorized oil and gas development on Federal lands within 13 Colorado BLM planning areas and the BLM NMFFO Planning Area (i.e., the 14 BLM Planning Areas) to air quality (AQ) and air quality related value (AQRV) impacts associated with the 2025 High, Low and Medium Development Scenarios. Emphasis is laid on 14 Colorado BLM Planning Areas while contributions of other source groups are also analyzed. The following sections describe the approach of the CARMMS 2.0 2025 CAMx source apportionment modeling and analysis. The results are presented in Chapter 5.

4.1 CARMMS Source Apportionment Modeling Approach

The CAMx Anthropogenic Precursor Culpability Assessment (APCA) version of the Ozone Source Apportionment Technology (OSAT) and the Particulate Source Apportionment Technology (PSAT) were used to obtain separate AQ and AQRV contributions due to BLM-authorized new oil and gas development on Federal lands for each of the 13 Colorado BLM Planning Areas and the BLM NMFFO Planning Area (i.e., the 14 BLM Planning Areas). The source apportionment modeling also obtained contributions from new oil and gas emissions on non-Federal lands, existing oil and gas emissions, and mining within the combined 14 BLM Planning Areas, oil and gas emissions within the 12 km CARMMS 2.0 domain outside the 14 BLM Planning Areas, remainder anthropogenic emissions and natural emissions (i.e., biogenic sources, fires, lightning, windblown dust and sea salt), as well as coal-fired and oil/gas-fired EGUs.

4.1.1 Overview of Source Apportionment Tools

The CAMx OSAT/APCA ozone and PSAT PM source apportionment tools use reactive tracers that are released from each Source Group for which contributions are desired. These reactive tracers operate in parallel to the host photochemical grid model accessing the model's transport, dispersion, chemistry and deposition algorithms. For example, the OSAT/APCA ozone source apportionment tools represents each Source Group's ozone contributions using four reactive tracers that represent the Source Groups VOC emissions (V), NO_X emissions (N) and ozone attributed to the Source Group that is formed under more VOC-limited (O3V) and NO_X-limited (O3N) conditions. At each time step and in each grid cell, ozone formed is allocated to the Source Groups based on the Source Groups relative contribution of VOC or more NO_X emissions to the total VOC or NO_X concentrations after determination of whether ozone formation is more VOC-limited or more NO_X-limited. The APCA ozone source apportionment tool differs from OSAT in that it recognizes that some precursor emissions are not controllable so redirects ozone formed from the uncontrollable to the controllable Source Group. For example, when ozone is formed under VOC-limited conditions due to the interaction between biogenic VOC and anthropogenic NO_X emissions, a case OSAT would assign the ozone formed to the biogenic emissions Source Group, APCA redirects the ozone formed to the anthropogenic emissions Source Group recognizing that biogenic VOC emissions are not controllable and without the anthropogenic NO_X the ozone would not have been generated. In a CAMx APCA source apportionment run, the first Source Category specified in the run is assumed to be the uncontrollable Source Group (typically natural emissions) and ozone will only be allocated to natural emissions when it is due to natural VOC and NO_X emissions interacting with each other

(e.g., ozone formed due to reactions between biogenic VOC and biogenic NOx). For the CARMMS 2.0 modeling, the natural emissions Source Group included biogenic, fires (wildfires, prescribed burns and agricultural burning), lightning, windblown dust and sea salt emissions. Although one could argue that emissions from prescribed burns and agricultural burning are not natural, emissions from wildfires dominate the fire emissions especially within the CARMMS 2.0 12 km domain.

For the CAMx PSAT PM source apportionment tool, there are several families of PM source apportionment tracers that can be run separately or together that track the different components of PM. Each of these families has a different number of reactive tracers to track the pathway from the PM precursor emissions to the ultimate PM compounds. The five different families of PSAT source apportionment are as follows (number of tracers in parenthesis): Sulfate-SO4 (2); Nitrate/Ammonium-NO3/NH4 (7); Primary PM (6); Secondary Organic Aerosol-SOA (20) and Mercury-Hg (3). For CARMMS, we used the SO4, NO3/NH4 and Primary PM PSAT families of tracers so that 15 total reactive tracers are needed to track PM contribution for each Source Group. The Hg PSAT family was not used because mercury is not a focus of CARMMS and O&G sources typically have negligible Hg emissions. There are five SOA precursors treated in CAMx: toluene and xylene (aromatics), isoprene, terpene and sesquiterpene with biogenic sources contributing a majority of the SOA. O&G VOC emissions are dominated by light VOCs that do not form any SOA. We examined the speciation of the O&G emissions and found the five VOC species that are SOA precursors account for approximately 0.1 percent of the O&G VOC emissions. Thus, O&G emission VOCs would have a negligible contribution to SOA so the SOA family of PSAT source apportionment tracers was not used. The CARMMS annual source apportionment runs take over a month to complete and use of the SOA PSAT family would have more than doubled the number of tracers. Thus, SOA is not included in the $PM_{2.5}$ and visibility impacts associated with Source Groups A through V that are based on the PSAT source apportionment modeling results. But SOA is included in the $PM_{2.5}$ and visibility impacts of total emissions from the 2025 and 2011 emission scenarios.

4.1.2 CARMMS Source Apportionment Configuration

The APCA version of the OSAT and the SO4, NO3/NH4 and Primary PM (i.e., no SOA) families of PSAT source apportionment was used to track the AQ/AQRV contributions of new O&G development on Federal lands in 14 separate BLM Planning Areas (Figure 4-1) for the 2025 High, Low and Medium Development Scenarios using the CARMMS 2.0 2011 12/4 km modeling platform. In total, in CARMMS 2.0, the 2025 CAMx source apportionment modeling tracked AQ/AQRV contributions for 23 (A-W) separate Source Categories in the order listed in Table 4-1. In addition, contributions from 11 (X-A8) additional combined source groups were obtained by combining separate individual source groups from CAMx source apportionment modeling (Table 4-2), to disclose impacts from a few categories of sources, such as the total contribution from new federal O&G in Colorado (X).

In addition to the CAMx source apportionment tool, another alternative approach, i.e., the so-called Bruce-Force approach, was also taken to calculate the total AQ/AQRV impact from new federal O&G in Colorado. Specifically, a “zero-out” CAMx simulation was conducted using emissions input that excluded the emissions from new O&G emissions in the 12 BLM planning

areas in Colorado (areas 2-13 in Table 4-1), to simulate the total concentrations without the emissions from new federal O&G in CO; the difference between the 2025 total concentrations the total concentrations without the emissions from new federal O&G in CO was used to represent the contribution from new federal O&G in CO. The result is presented as a source group X1 (Table 4-2), which is equivalent to source group X but by using a different approach. Note that Table 4-1 has unique source groups applied in CAMx; additional groups (for example, all oil and gas) may be generated through combinations of these groups.

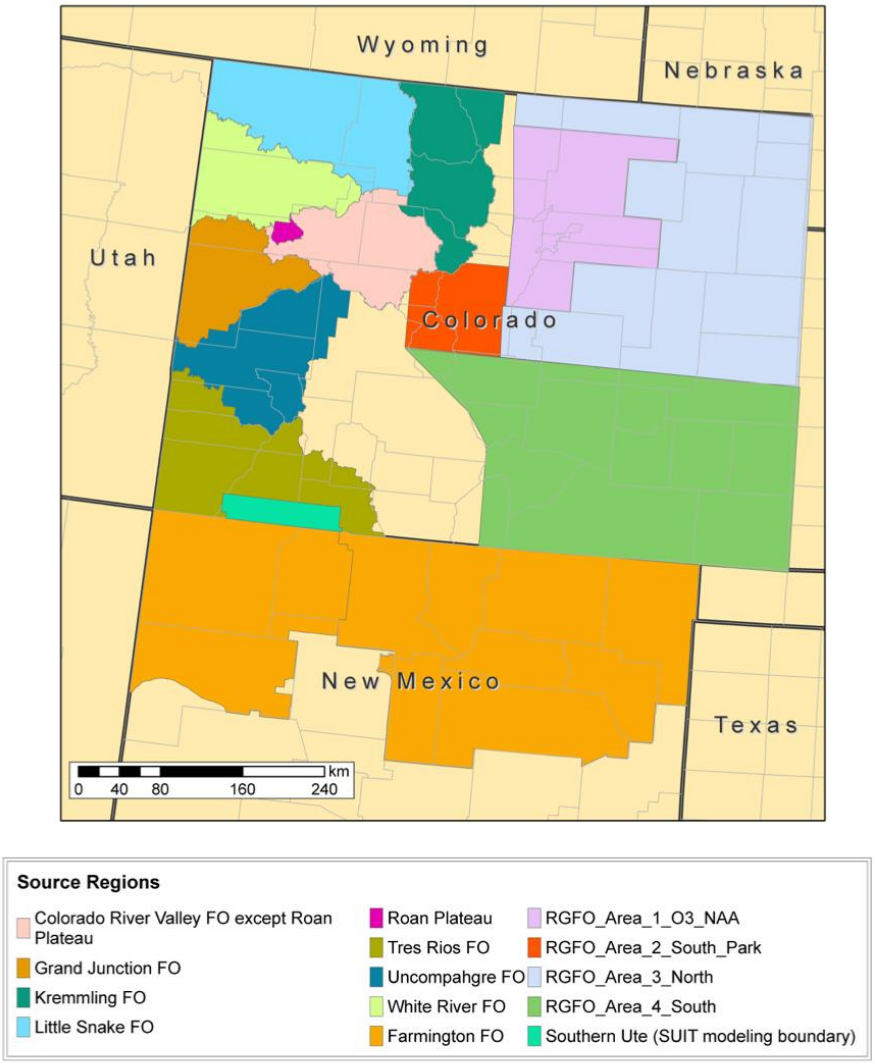

Figure 4-1. Colorado BLM planning areas and New Mexico planning area (the 14 BLM Planning Areas) where separate contributions of new O&G development on Federal lands were obtained for 2025 source apportionment modeling.

Table 4-1. Ordering of the 23 Source Categories used in the CAMx 2025 source apportionment modeling in CARMMS 2.0.

Reported Source Category	Definition	CAMx source group(s)
A	Natural emissions (combined biogenic, fires, lightning, sea salt and windblown dust)	1
B	Little Snake FO	2
C	White River FO	3
D	Colorado River Valley FO (CRVFO)	4
E	Roan Plateau Planning area portion of CRVFO	5
F	Grand Junction FO	6
G	Uncompahgre FO	7
H	Tres Rios FO	8
I	Kremmling FO	9
J	RGFO #1 (all area within the Denver / Front Range Ozone NAA; future Federal O&G)	10
K	RGFO #2 (all area outside the Denver / Front Range Ozone NAA and within the approximate northern half of the RGFO; future Federal O&G)	11
L	RGFO #3 (South Park area; future Federal O&G)	12
M	RGFO #4 (approximately the southern half of RGFO outside the other source apportionment areas; future Federal O&G)	13
N	Southern Ute Indian Tribe Supplemental Environmental Impact Statement for Shale Formation Oil and Gas Plan of Development (SUIT; all wells assumed non-federal)	14
O	New Mexico Farmington Field Office (NMFFO) (future Federal O&G)	15
P	Combined future non-Federal O&G from BLM Field Office Planning Areas in CO and NMFFO	16
Q	Combined Existing O&G from BLM Planning Areas in CO (federal and non-Federal O&G)	17
R	Mining from BLM Planning Areas	18
S	All O&G in 12 km domain outside the BLM Planning Areas of CO and NMFFO (existing and new; non-federal and federal)	19
T	Remaining anthropogenic emissions (on-road and non-road mobile, non-EGU point and area sources everywhere in 12 km domain)	20
U	Coal EGU Colorado + New Mexico	21
V	Oil/Gas EGU Colorado + New Mexico	22
W	All Other EGUs in 12 km domain	23

4.2 Post-Processing of the CAMx 2025 Source Apportionment Modeling Results

The CAMx 2025 total concentrations results were post-processed for comparison to the applicable ambient air quality standards as listed in Table 4-3. Gas-phase species were converted from parts per million (ppm) to µg/m^3 using the conversion factor recommended in the Colorado Department of Health and Environment (CDPHE) air permit modeling guidance[14]. The incremental AQ and AQRV impacts due to each of the 35 Source Groups listed in Table 4-1 and Table 4-2 were reported in CARMMS 2.0.

Table 4-2. Combined Source apportionment post-processing source Groups with separate AQ/AQRV impacts at Class I and sensitive Class II areas disclosed for the 2025 emission scenarios in CARMMS 2.0.

Reported Source Category	Definition	CAMx source group(s)
X	Total new federal O&G in CO	Sum of 2 - 13
Y	New total CRVFO	4 + 5
Z	New total RGFO	10+11+12+13
A1	All new O&G in CO plus new non-federal FFO	X + 14 + 16
A2	New federal O&G + new Mining in CO (R in CARMMS 1.5)	X + 18
A3	New federal O&G + new non-federal O&G + Mining in CO (S in CARMMS 1.5; approximate as it also includes new non-fed FFO)	A1 + 18
A4	All EGUs in CO and NM	21 + 22
A5	2025 BC	BC tracer
A6	2025 Total	2025 Core model output
A7	2011 Total	2011 Core model output
X1	Total new federal O& G in CO using Brute-Force zero-out run	Difference between A7 and zero-out run

The 35 Source Groups listed in Table 4-1 and Table 4-2 consist of the following sources:

(A) Natural emissions (biogenic, fires, lightning, WBD and sea salt).

(B-O) New Federal O&G from each of the 14 BLM Planning Areas as shown in Figure 4-1.

(O) New Federal O&G from the New Mexico Farmington Field Office.

(P) Combined future non-Federal O&G from 14 BLM Field Office Planning Areas.

(Q) Combined existing O&G from BLM Planning Areas.

(R) Combined mining emissions from BLM Planning Areas.

[14] C [ppm] = C [µg/m^3] / (40.9 x MW), where MW = molecular weight in g/mole. This formula assumes 1 atmosphere pressure and 298 K temperature. http://www.colorado.gov/airquality/permits/guide.pdf

(S) All O&G in 12 km domain outside the BLM Planning Areas of CO and NMFFO

(T) Remaining anthropogenic emissions (on-road and non-road mobile, non-EGU point and area sources everywhere in 12 km domain).

(U-W) Coal (U) and O&G (V) EGUs in Colorado and New Mexico, and all other EGUs in the 12 km domain (W).

(X) Total new Federal O&G in Colorado.

(Y) Total emissions from Colorado River Valley FO (CRVFO)

(Z) Total emissions from RGFO (#1 - #4)

(A1) All new O&G in CO plus new non-federal FFO (doesn't include new fed FFO), i.e., New federal O&G in CO + New SUIT shale + New state/private (non-fed) O&G in Colorado and FFO.

(A2) New federal O&G and new Mining in CO.

(A3) Total emissions from new federal O&G, new non-federal O&G and new Mining in CO (this is approximate as it also includes new non-fed FFO).

(A4) All EGUs in CO and NM.

(A5) Contributions from 2025 boundary conditions (BC), i.e., sources outside the 12 km domain.

(A6) All emissions from the 2025 CAMx simulation (total concentrations).

(A7) All emissions from the 2011 CAMx simulation (total concentrations).

(X1) Total new federal O& G in CO using Brute-Force zero-out run (calculated as the difference between 2025 CAMx total concentrations and the zero-out run for each of the High, Low and Medium scenarios). It is equivalent to X but by using a different modeling approach.

Table 4-3 shows the national and state ambient air quality standards and PSD concentration increments that are used in the air quality impact assessment.

Table 4-3. Applicable National and State Ambient Air Quality Standards and PSD concentration increments (bold indicates units in which standard was defined, conversion to ppm/ppb following CDPHE modeling guidance).

4.3 Class I and Sensitive Class II Areas for Analysis

The AQ/AQRV impacts due to O&G development on Federal lands within the Colorado BLM Planning Areas were assessed for the Class I areas and sensitive Class II areas identified in CARMMS 1.0/1.5 (Ramboll Environ and Kleinfelder, 2016a, Parker and Morris, 2014) within the CARMMS 2.0 12/4 km modeling domain. GIS analysis was performed to determine the grid cell definition of the identified Class I/II areas within the CARMMS 2.0 12/4 km modeling domain. Sensitive lakes in the region were also identified.

4.3.1 Final Class I and Sensitive Class II Areas

The Class I areas where air quality and AQRV impacts were calculated within the 12/4 km CARMMS 2.0 modeling domain are displayed in Figure 4-2 and listed in Table 4-4. The sensitive Class II areas used in the CARMMS post-processing are displayed in Figures 4-3a – 4-3c and listed in Table 4-5. Note that several of the Class I areas are portions of a sensitive Class II area. In total, the CARMMS modeling results were post-processed using 26 and 58 Class I and sensitive Class II areas, respectively. Details on how the sensitive Class II areas were defined are provided in Parker and Morris (2014). Note that the Colorado side of Dinosaur National Monument is considered PSD Class I for just SO_2. Sensitive lakes in the region where acid neutralizing capacity (ANC) calculations are made are listed in Table 4-6.

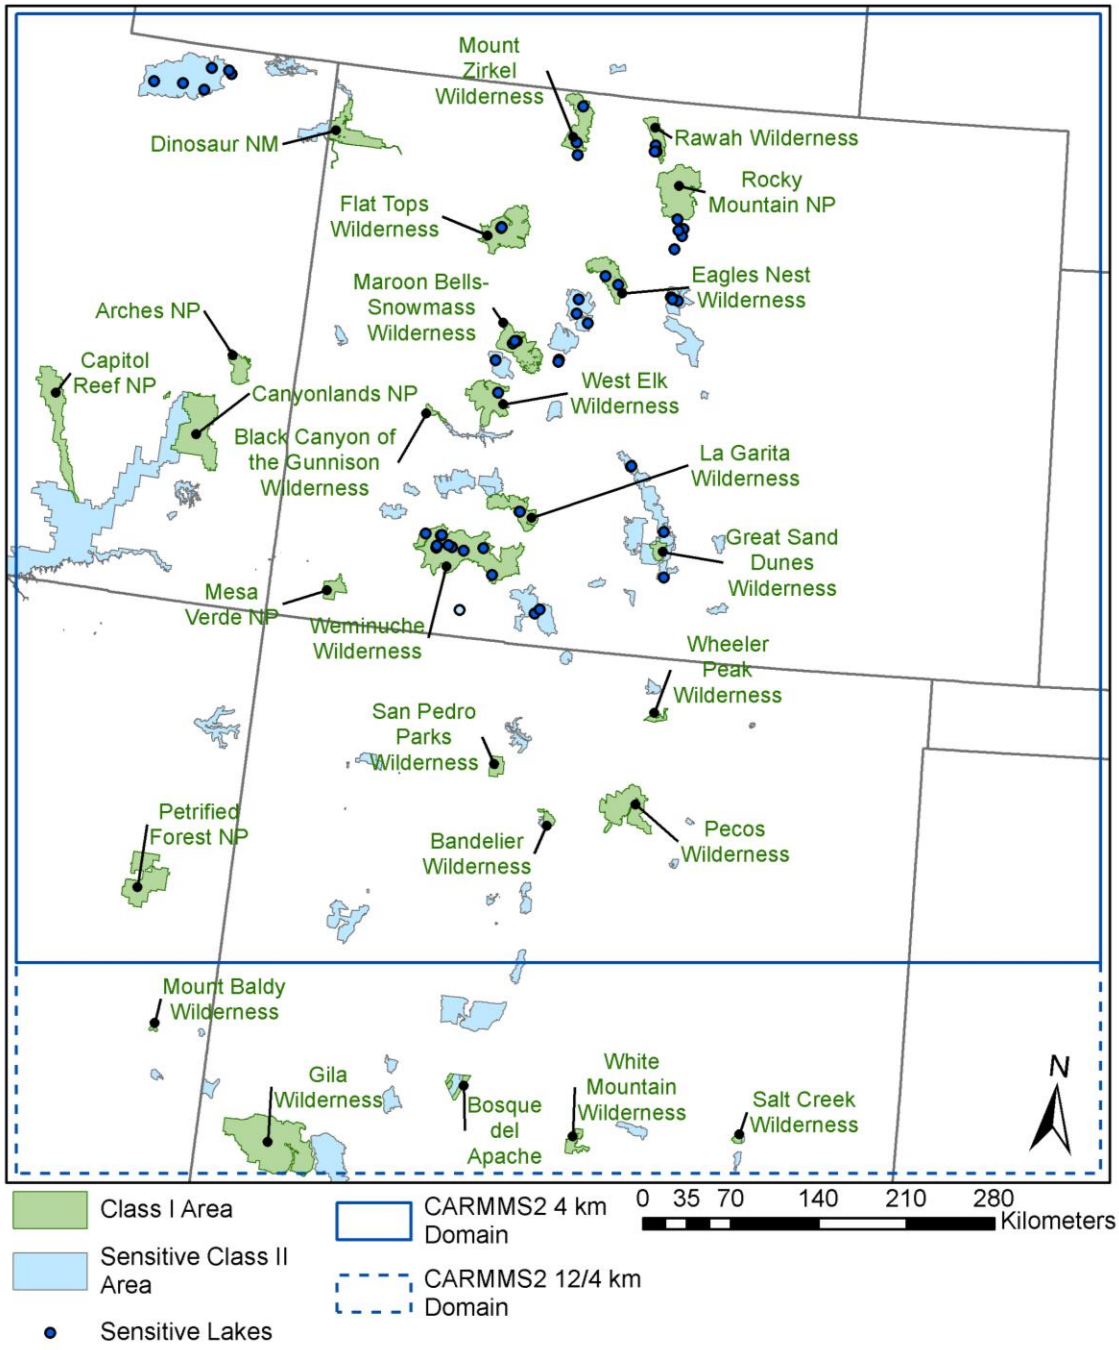

Figure 4-2. Locations of Class I (light green) and sensitive Class II (light blue) areas where air quality and AQRV impacts were assessed as well as sensitive lakes (black dots) with ANC calculations. Class I areas are labeled, while sensitive Class II areas and sensitive lakes are not.

4.3.2 Class I and Sensitive Class II Area Grid Cell Assignments

Determining the grid cells that represent the Class I/II areas was achieved with Graphical Information System (GIS) software, and was performed by intersecting the CAMx model grid cells with GIS shapefiles that define the Class I/II boundaries. Different GIS tools are available to perform the intersection that assigns a Class I/II designation to each grid cell, and different input shapefiles defining the boundaries are also available.

To generate the grid cells for the final analysis, we used official Class I boundary shapefiles that are available for download from the NPS website[15]. The GIS tool "spatial join" was used to assign a Class I/II area to each CAMx grid cell if any part of the Class I/II area intersects the grid cell. Then, a cell area threshold was applied to remove those grid cells in which in the Class I/II area made up less than 5% of the total cell area. However, the threshold was only applied if the Class I/II area would still be represented by other grid cells. In other words, the threshold was

[15] http://www.nature.nps.gov/air/maps/classiloc.cfm

not applied to areas whose geographical extent was too small to comprise more than 5% of any grid cell, such as the Aztec Ruins NM. In addition, for the final processing, attention was paid to grid cells that cover more than one Class I/II area, in those cases, a particular grid cell was used twice to represent 2 different neighboring Class I/II areas.

4.4 Ambient Concentration Analysis using Absolute Modeling Results

Modeled concentrations predicted by the CAMx due to all sources were compared against national and state standards (NAAQS, CAAQS and NMAAQS) throughout the 4 km modeling domain. When exceedances of the ozone or $PM_{2.5}$ NAAQS are estimated, the APCA and PSAT source apportionment results was used to determine the contribution of emissions from each of the Source Groups to determine the major cause of the modeled exceedance. The incremental air quality concentration contribution due to emissions from oil and gas on Federal lands at Class I and sensitive Class II areas for each BLM planning area were compared to applicable PSD increments (see Table 4-3). The PSD demonstrations are for information only and are not regulatory PSD Increment consumption analyses, which would be completed as necessary by the relevant state or other agency.

4.5 Ambient Concentration Analysis using Relative Modeling Results

EPA's modeling guidance recommends using the PGM modeling results in a relative fashion when comparing future year modeling results to the ozone and $PM_{2.5}$ NAAQS (EPA, 2007). The relative change in the PGM concentrations between the current and future year simulations are used to scale the observed current year ozone or $PM_{2.5}$ Base Design Value (DVB) to obtain a projected future year Design Value (DVF). The model derived scaling factors are called Relative Response Factors (RRFs) and are based on the ratio of future year to current year modeling results:

$$DVF = DVB \times RRF$$

EPA's PGM modeling guidance provides recommended procedures for calculating DVBs and RRFs (EPA, 2007) that have been implemented in EPA's Modeled Attainment Test Software (MATS[16]; Abt, 2012). The MATS projection tool was used with the CAMx 2011 Base Case and 2025 High, Low and Medium Development Scenarios modeling results to project future year ozone DVFs that were compared to the NAAQS. MATS also has a capability of projecting $PM_{2.5}$ DVFs but there is much less observed $PM_{2.5}$ data in the region so such projections would be extremely limited, so MATS was not used for $PM_{2.5}$. The MATS default settings for making future year ozone projections were used that includes using a DVB based on an average of three-years of Design Values (DVs) centered on the Base Case modeling year (2011) and constructing RRFs using at least 10 days of modeling results. As the Base Case year is 2011, then this means using a DVB based on DVs from the following 3-year periods, 2009-2011, 2010-2012 and 2011-2013.

4.6 Visibility Analysis

Visibility impacts were calculated for new oil and gas and mining emissions on Federal lands within each BLM Planning Areas as well as for cumulative emissions sources. The approach used the incremental concentrations as quantified by the CAMx PSAT tool simulation of oil and gas and mining activities within each BLM planning area. Changes in light extinction from CAMx

[16] http://www.epa.gov/ttn/scram/modelingapps_mats.htm

model concentration increments due to emissions from oil and gas and other activity emissions were calculated for each day at grid cells that intersect Class I and sensitive Class II areas within the 12/4 km modeling domain (see Section 4.3.2). The FLAG (2010) procedures were used in the incremental BLM planning area-specific visibility assessment analysis.

The visibility evaluation metric used in this analysis is based on the Haze Index which is measured in deciview (dv) units and is defined as follows:

$$HI = 10 \times \ln[b_{ext}/10]$$

b_{ext} is the atmospheric light extinction measured in inverse megameters (Mm^{-1}) and is calculated primarily from atmospheric concentrations of particulates. A more intuitive measure of haze is visual range (VR), which is defined as the distance at which a large black object just disappears from view, and is measured in km. Visual range is related to b_{ext} by the formula VR = 3912 / b_{ext}. Visual range will not be used as a threshold in the analysis, but could be back-calculated from extinction to give a more easily understood visibility metric.

The incremental concentrations due to BLM planning area emissions were added to background concentrations in the extinction equation (b_{ext}) and the difference between the Haze Index with added BLM planning area concentrations to the Haze Index based solely on background concentrations is calculated. This quantity is the change in Haze Index, which is referred to as "delta deciview" (Δdv) :

$$\Delta dv = 10 \times \ln[b_{ext(BLM+background)}/10] - 10 \times \ln[b_{ext(background)}/10]$$

$$\Delta dv = 10 \times \ln[b_{ext(BLM+background)}/b_{ext(background)}]$$

Here $b_{ext(BLM+background)}$ refers to atmospheric light extinction due to oil and gas and other activities in each BLM planning area plus background concentrations, and $b_{ext(background)}$ refers to atmospheric light extinction due to background concentrations only.

For each individual BLM Planning Area, the estimated visibility degradation at the Class I areas and sensitive Class II areas due to new O&G emissions on Federal lands are presented in terms of the number of days that exceed a threshold change in deciview (Δdv) relative to background conditions. In the next section we describe the method for calculating the extinction, b_{ext}.

4.6.1 IMPROVE Reconstructed Mass Extinction Equations

The FLAG (2010) procedures for evaluating visibility impacts at Class I areas use the revised IMPROVE reconstructed mass extinction equation to convert PM species in μgm^{-3} to light extinction (b_{ext}) in inverse megameters (Mm^{-1}) as follows:

$$b_{ext} = b_{SO4} + b_{NO3} + b_{EC} + b_{OCM} + b_{Soil} + b_{PMC} + b_{SeaSalt} + b_{Rayleigh} + b_{NO2}$$

where

$$b_{SO4} = 2.2 \times f_S(RH) \times [\text{Small Sulfate}] + 4.8 \times f_L(RH) \times [\text{Large Sulfate}]$$

$$b_{NO3} = 2.4 \times f_S(RH) \times [\text{Small Nitrate}] + 5.1 \times f_L(RH) \times [\text{Large Nitrate}]$$

$$b_{OCM} = 2.8 \times [\text{Small Organic Mass}] + 6.1 \times [\text{Large Organic Mass}]$$

$$b_{EC} = 10 \times [\text{Elemental Carbon}]$$

$$b_{Soil} = 1 \times [\text{Fine Soil}]$$

$$b_{CM} = 0.6 \times [\text{Coarse Mass}]$$

$$b_{SeaSalt} = 1.7 \times f_{SS}(RH) \times [\text{Sea Salt}]$$

$$b_{Rayleigh} = \text{Rayleigh Scattering (Site-specific)}$$

$$b_{NO2} = 0.33 \times [NO_2 \text{ (ppb)}] \text{ {or as: } } 0.1755 \times [NO_2 \text{ } (\mu g/m^3)]\}.$$

f(RH) are relative humidity adjustment factors that account for the fact that sulfate, nitrate and sea salt aerosols are hygroscopic and are more effective at scattering radiation at higher relative humidity. FLAG (2010) recommends using monthly average f(RH) values rather than the hourly averages recommended in the previous FLAG (2000) guidance document in order to moderate the effects of extreme weather events on the visibility results.

The revised IMPROVE equation treats "large sulfate" and "small sulfate" separately because large and small aerosols affect an incoming beam of light differently. However, the IMPROVE measurements do not separately measure large and small sulfate; they measure only the total $PM_{2.5}$ sulfate. Similarly, CAMx writes out a single concentration of particulate sulfate for each grid cell. Part of the definition of the new IMPROVE equation is a procedure for calculating the large and small sulfate contributions based on the magnitude of the model output sulfate concentrations; the procedure is documented in FLAG (2010). The sulfate concentration magnitude is used as a surrogate for distinguishing between large and small sulfate concentrations. For a given grid cell, the large and small sulfate contributions are calculated from the model output sulfate (which is the "Total Sulfate" referred to in the FLAG (2010) guidance) as:

For Total Sulfate < 20 $\mu g/m^3$:

$$[\text{Large Sulfate}] = ([\text{Total Sulfate}] / 20\ \mu g/m^3) \times [\text{Total Sulfate}]$$

For Total Sulfate ≥ 20 $\mu g/m^3$:

$$[\text{Large Sulfate}] = [\text{Total Sulfate}]$$

For all values of Total Sulfate:

$$[\text{Small Sulfate}] = [\text{Total Sulfate}] - [\text{Large Sulfate}]$$

The procedure is identical for nitrate and organic mass. Sulfate, nitrate and organic mass concentrations for the western U.S. are expected to be mainly in the small fraction.

The PSAT source apportionment algorithm does not separately track NO_2 concentrations but instead tracks total reactive nitrogen (RGN) that consistent mainly of NO plus NO_2. Thus for each hour and each grid cell representing a Class I/II area, a Source Group's incremental PSAT RGN contribution is converted to NO_2 by multiplying by the total (all emissions) CAMx model NO_2/RGN concentration ratio, which is then used in the IMPROVE visibility equation.

Although sodium and particulate chloride are treated in the CAMx core model, these species are not carried in the CAMx PSAT tool; neglecting sea salt in the visibility calculations in the 4 km CARMMS impact assessment domains does not compromise the accuracy of the analysis as IMPROVE measurements show that sea salt concentrations are negligible in this inland area and there would be no sea salt associated with any of the O&G emissions.

Predicted daily average modeled concentrations due to each BLM planning area for grid cells containing Class I and sensitive Class II area receptors were processed using the revised IMPROVE reconstructed mass extinction equation FLAG (2010) to obtain changes in b_{ext} at each sensitive receptor area which are then converted to deciview and reported.

The FLAG (2010) method was used to estimate the visibility impacts from each Colorado and northern New Mexico BLM Planning Area. This method used the revised IMPROVE equation together with annual average natural conditions (see Table 6 in FLAG, 2010) and monthly relative humidity factors for each Class I area (see Tables 7-9 in FLAG, 2010). The Δdv was calculated for each grid cell that overlaps a Class I or sensitive Class II area for each day of the annual CAMx run. The highest Δdv across all grid cells overlapping a Class I or sensitive Class II area was selected to represent the daily value at that Class I/II area. Visibility impacts due to new O&G emissions on Federal lands within each BLM Planning Areas that are more than 0.5 and 1.0 dv are reported.

4.6.2 Cumulative Visibility

The cumulative visibility impacts due to the development of oil and gas and other (e.g., mining) activities on all BLM Planning Areas were assessed following the recommendations from the FWS and NPS that was outlined in their February 10, 2012 letter to the Wyoming Department of Environmental Quality on recommended cumulative visibility method for the Continental Divide-Creston gas infill development EIS (FWS and NPS, 2012) and subsequent conversations with the FLMs. This approach is based on an abbreviated regional haze rule method that estimates the future year visibility at Class I and sensitive Class II areas for the average of the Worst 20% (W20%) and Best 20% (B20%) visibility days with and without the effects of the cumulative emissions on visibility impairment. The cumulative visibility impacts used CAMx model output from the 2011 Base Case and 2025 emissions scenarios in conjunction with monitoring data to produce cumulative visibility impacts at each Class I area in the CARMMS domain. EPA's Modeled Attainment Test Software (MATS[17]) was used to make the 2025 visibility projections for the W20% and B20% days. The basic steps in the recommended cumulative visibility method are as follows (FWS and NPS, 2012):

[17] http://www.epa.gov/ttn/scram/modelingapps_mats.htm

5. Calculate the observed average 2011 current year cumulative visibility impact using the Haze Index (HI, in deciviews) at each Class I or associated sensitive Class II area to determine the 20% of days with the worst and 20% of days with the best visibility. The intent is to incorporate 5 years of monitoring data surrounding the 2011 Base Case year, which would include 2009-2013. MATS uses the IMPROVE data associated with each Class I area and modeling results at the location of the IMPROVE monitoring site.

2. Estimate the relative response factors (RRFs) for each component of $PM_{2.5}$ and for coarse mass (CM) corresponding to the new IMPROVE visibility algorithm using the CAMx 2011 and 2025 model output.

3. Using the RRFs and ambient data, calculate 2025 future-year daily concentration data for the B20% and W20% days using the CAMx 2011 Base Case and 2025 standard model concentration estimates and PSAT source apportionment modeling results two ways:

4. 2025 Total Emissions: Use total 2025 High, Low and Medium Development Scenario CAMx concentration results due to all emissions;

5. 2025 No Cumulative Emissions: Use PSAT source apportionment results to eliminate contributions of PM concentrations associated with combined emission scenarios corresponding to Source Groups X, A1, A2, A3, A4, and X1 in Table 4-2.

6. Use the information in step 3 to calculate the average 2025 visibility for the 20% Best and 20% Worst visibility days and the 2025 emissions.

7. Assess the average differences in cumulative visibility impacts for the four combined scenarios and also compare with the current observed Baseline visibility conditions.

4.7 Sulfur and Nitrogen Deposition

CAMx-predicted wet and dry fluxes of sulfur- and nitrogen-containing species were processed to estimate total annual sulfur (S) and nitrogen (N) deposition values at each Class I and sensitive Class II area as well as at each acid sensitive lake. The Maximum annual S and N deposition values from any grid cell that intersects a Class I or sensitive Class II receptor area was used to represent deposition for that area, in addition to the Average annual deposition values of all grid cells that intersect a Class I or sensitive Class II receptor area. Maximum and Average predicted S and N deposition impacts were estimated separately for each BLM planning area and together across all BLM planning areas using the Source Groups in Table 4-2c.

Nitrogen deposition impacts were calculated by taking the sum of the nitrogen contained in the fluxes of all nitrogen species modeled by the CAMx PSAT source apportionment tool. CAMx species used in the nitrogen deposition flux calculation are: reactive gaseous nitrate species, RGN (NO, NO_2, NO_3 radical, HONO, N_2O_5), TPN (PAN, PANX, PNA), organic nitrates (NTR), particulate nitrate formed from primary emissions plus secondarily formed particulate nitrate (NO_3), gaseous nitric acid (HNO_3), gaseous ammonia (NH_3) and particulate ammonium (NH_4).

CAMx species used in the sulfur deposition calculation are primarily sulfur dioxide emissions (SO_2) and particulate sulfate ion from primary emissions plus secondarily formed sulfate (SO_4).

FLAG (2010) recommends that applicable sources assess impacts of nitrogen and sulfur deposition at Class I areas. This guidance recognizes the importance of establishing critical deposition loading values ("Critical Loads") for each specific Class I area as these Critical Loads are completely dependent on local atmospheric, aquatic and terrestrial conditions and chemistry. Critical Load thresholds are essentially a level of atmospheric pollutant deposition below which negative ecosystem effects are not likely to occur. FLAG (2010) does not include any Critical Load levels for specific Class I areas and refers to site-specific critical load information on FLM websites for each area of concern. This guidance does, however recommend the use of deposition analysis thresholds (DATs[18]) developed by the National Park Service and the Fish and Wildlife Service. The DATs represent screening level values for nitrogen and sulfur deposition for individual projects with deposition impacts below the DATS considered negligible. Note that DATs are Project-level thresholds. DAT have been established for both nitrogen and sulfur deposition and in western Class I areas they are 0.005 kilograms per hectare per year (kg/ha-yr) for both nitrogen and sulfur deposition. As a screening analysis, results for oil and gas and mining activities for each BLM planning area, which is Source Groups A through P were separately compared to the DATs. Comparison of deposition impacts from combined Source Groups to the DAT is not appropriate.

For the combined Source Groups and total 2011 and 2025 emissions Source Groups W and X, the annual nitrogen and sulfur deposition were compared against Critical Load values established for the Rocky Mountain region to assess total deposition impacts. The NPS has provided recent information on nitrogen critical load values applicable for Wyoming and Colorado Class I and sensitive Class II areas (NPS, 2014). For Class I and sensitive Class II areas in Wyoming a critical load value of 2.2 kg/ha-yr for nitrogen deposition (estimated from a wet deposition critical load value of 1.4 kg N/ha-yr) is applicable, based on research conducted by Saros et. al.(2010) in the eastern Sierra Nevada and Greater Yellowstone ecosystems. This is a critical load value that is protective of high elevation surface waters. For Colorado Class I and sensitive Class II areas (with the exception of Dinosaur National Monument) a critical load value 2.3 kg N/ha-yr is applicable for total nitrogen deposition, based on research conducted by Jill Baron (Baron 2006) that estimated 1.5 kg/ha-yr as a critical loading value for wet nitrogen deposition for high-elevation lakes in Rocky Mountain National Park, Colorado. For Dinosaur National Monument, which is an arid region, a nitrogen deposition critical load value is based on research conducted by Pardo et al. (2011) which concluded that the cumulative critical load necessary to protect shrublands and lichen communities in Dinosaur NM is 3 kg N/ha/year.

For sulfur deposition, the critical load threshold published by Fox et al. (Fox 1989) for total sulfur deposition of 5 kg/ha-yr, for the Bob Marshall Wilderness Area in Montana and Bridger Wilderness Area in Wyoming, was used as critical load threshold for each of the Class I and sensitive Class II areas.

[18] http://www.nature.nps.gov/air/Pubs/pdf/flag/nsDATGuidance.pdf

In summary, we will compare the total annual sulfur and nitrogen deposition amounts for the cumulative Source Groups Q through X to the following Critical Load values:

Nitrogen

- Wyoming – 2.2 kg/ha-yr
- Colorado – 2.3 kg/ha-yr, except for Dinosaur Monument that will use 3.0 kg/ha-yr

Sulfur

- 5.0 kg/ha-yr – all areas

4.8 Acid Neutralizing Capacity

In addition to calculation of total deposition fluxes, an additional analysis was performed to assess the change in water chemistry associated with atmospheric deposition from BLM oil and gas and mining activities and cumulative sources for each of the sensitive lakes listed in Table 4-5. This analysis assesses the change in the acid neutralizing capacity (ANC) of sensitive lakes. An estimate of potential changes in ANC was made by following the procedure developed by the USFS Rocky Mountain Region (USFS, 2000). Predicted changes in ANC are compared with the threshold (10 percent change in ANC for lakes with background ANC values greater than 25 micro equivalents per liter [µeq/L], and no more than a 1 µeq/L change in ANC for lakes with background ANC values equal to or less than 25 µeq/L). A list of sensitive lakes was obtained from the USFS (Table 4-5). The most recent lake chemistry background ANC data was obtained from the VIEWS website for each of the sensitive lakes in the 12/4 km CARMMS 2.0 modeling domain.

4.9 W126 Cumulative Ozone Exposure Index

Vegetation response to ozone as a stress to growth is correlated not only with absolute amount of ozone but also with the amount of time exposed during daytime photosynthesis. To quantify this stress, several ozone exposure metrics have been proposed as another secondary standard of ozone. These are Sum of ozone greater than 60 ppb (SUM60), Accumulated Ozone exposure over a Threshold of 40 ppb (AOT40), and Cumulative peak-weighted index (W126), and all of three metrics has the same unit of ppm-hours. Among them, W126 is reported as representing most realistically the vegetation's response to ozone using a sigmoidal weight function to ozone concentration.

There is no official threshold set by US EPA for the ozone exposure metrics while Canada and the United Nations Economic Commission for Europe (UN/ECE) have set thresholds for SUM60 and AOT40, respectively. EPA was taking comments on the annual W126 in the range of 13-17 ppm-hours and was also seeking comment on defining a target protection level of the annual W126 value as low as 7 to 13 ppm-hours. Clean Air Scientific Advisory Committee (CASAC) recommends the annual W126 level be within 7 to 15 ppm-hours.

To calculate W126, three steps as follows were taken:

1. Calculate daily W126 for 12 hour from 8 AM to 8 PM based on Local Standard Time.

2. Sum the daily W126 for consecutive 3 months from starting month of ozone season, April chosen in this project. Thus, the first 3-month sum includes April, May, and July. Continue getting the 3-month sum of daily W126 until the ending month of the 3 month becomes the end of ozone season, October selected in this project. Thus, the last 3-month sum includes August, September, and October.

3. Find maximum among the five three-month sums, and this is annual W126.

The official annual W126 based on observation is the average of three years. However, the CAMx run is conducted only for one year so only one year is used in this project.

5.0 2025 MODELING RESULTS

In this Chapter we present the CARMMS modeling results for the 2025 High, Low and Medium Development Scenarios following the procedures given in Chapter 4 using examples from the 35 Source Groups listed in Table 4-1 and Table 4-2. Electronic attachments are provided that contain modeling results for all of the Source Groups with summaries provided in this Chapter. In this Chapter we present results for:

(X, X1) Total new O&G on Federal lands in BLM planning areas in CO, by CAMx source apportionment modeling (X) and Brute-Force approach (X1)

and one or more of the following Source Groups:

(C) New O&G on Federal lands within the BLM White River Field Office Planning Area;

(D) New O&G on Federal lands within the BLM Colorado River Valley Field Office (CRVFO) Planning Area;

(J) New O&G on Federal lands within the BLM RGFO #1 (all area within the Denver / Front Range Ozone NAA) Planning Area;

(P) Combined future O&G from non-Federal lands within the BLM Field Office Planning Areas;

(Q) Combined existing Federal and non-Federal O&G from BLM Planning Areas;

(S) All O&G (existing and new on Federal and non-Federal lands) in 12 km domain outside the BLM Planning Areas;

(T) Remaining anthropogenic emissions (on-road and non-road mobile, non-EGU point and area sources everywhere in 12 km domain);

(A1) All new O&G in CO plus new non-federal FFO;

(A2) New federal O&G + new Mining in CO;

(A3) New federal O&G + new non-federal O&G + Mining in CO;

(A4) All EGUs in CO and NM.

The contributions from the rest of the Source Groups are provided in the interactive electronic attachments.

5.1 PSD Pollutant Concentration Impacts at Class I and Sensitive Class II Areas

Attachment A-1, A-2 and A-3 are three Excel spreadsheets that contain the contributions of emissions from each Source Group listed in Table 4-1 and Table 4-2 to pollutant concentrations at the 27 Class I (Table 4-4) and 58 sensitive Class II (Table 4-5) areas for the 2025 High, Low and Medium Development Scenarios, respectively. Results are presented for each PSD pollutant and averaging time given in Table 4-3. Attachment A contains two pivot table sheets:

The first pivot table sheet is "Summary" that lists the impacts of a user selected Source Group to all PSD pollutants across all Class I/II areas. It is controlled by selecting the Source Group in cell B1 and whether contributions of the maximum receptor or average across all receptors in a Class I/II area is desired in cell B2; we always select the "Maximum" option. If a concentration at a Class I or sensitive Class II area is above the, respectively, PSD Class I or II Increments, the cell is shaded yellow.

The second pivot table sheet is "MaxImpact" and for a user-selected PSD pollutant it lists the maximum concentration impact at any Class I and sensitive Class II area due to emissions from each Source Group along with the percentage the concentration is of the PSD Increment and the Class I and II area where the maximum occurs. The pivot table is controlled by selecting the pollutant and averaging time in cell B1 and whether maximum or average concentrations across the Class I/II area is desired in cell B2.

The sheet "Readme" has a brief explanation of the sheets in the spreadsheet and maps for the locations of the Class I and sensitive Class II areas.

The PSD incremental concentrations are reported for informational purposes only and the analyses presented in this section are not a comprehensive PSD increment consumption assessment; that assessment must be performed by the appropriate state or federal agency.

5.1.1 Maximum PSD Concentration Impacts at any Class I or II Area

EPA has defined PSD Concentrations Increments for Class I and II areas for 8 different pollutant concentration/averaging time combinations (see Table 4-3). In this section we present the "Maximum" PSD concentration impacts at Class I and sensitive Class II areas due to each of the relevant 35 Source Groups from Table 4-1 and Table 4-2 (i.e., from the MaxImpact sheet in Attachments A-1 and A-2). The modeled impacts are based on the CAMx PSAT source apportionment contributions (or Brute-Force modeling analysis results for Source Group X1). For short-term averaging times (i.e., not annual), the highest second high concentration at each Class I/II area is selected for comparison with the PSD increment.

5.1.1.1 Annual NO_2 PSD Concentrations

The maximum contribution to annual NO_2 concentrations at any Class I or sensitive Class II area due to emissions from the 35 Source Groups for the 2025 High, Low and Medium Development Scenarios are shown in Table 5-1, which was obtained from the MaxImpact sheet in Attachments A-1, A-2 and A-3. The Class I and II PSD Increments for annual NO_2 are 2.5 and 25 $\mu g/m^3$, respectively. The annual NO_2 contributions from each of the individual BLM Planning Areas in Colorado and northern New Mexico (i.e., Source Groups B through O) are all below the

annual NO_2 PSD Increment in all Class I and sensitive Class II areas for all three 2025 emission scenarios. The BLM Planning Area with the highest annual NO_2 concentration contribution to any Class I area is the BLM Colorado White River Field Office Planning Area whose annual NO_2 concentration contribution at Dinosaur National Monument (NM) for the 2025 High Development Scenarios is 0.50 $\mu g/m^3$, which represents 20% of the Class I area Increment. The mitigation in the 2025 Medium Development Scenario reduces this impact by 13% to 0.432 $\mu g/m^3$; this represents 17% of the PSD Class I area annual NO_2 increment. The corresponding White River FO annual NO_2 impact for the Low Development Scenario is 0.06 $\mu g/m^3$; this represents 2% of the Class I increment. The maximum annual NO_2 contribution at any Class I area from any other of the 14 BLM Planning Areas are not greater than 3% of the Class I area NO_2 PSD Increment.

The highest annual NO_2 concentration at any sensitive Class II area due to new O&G emissions on Federal lands in any of the 14 BLM Planning Areas in the High Development Scenario is due the New Mexico Farmington Field Office (NMFFO) with a 1.7 $\mu g/m^3$ annual NO_2 concentration at the Aztec Ruins Class II area that represents 7% of the PSD Class II area Increment. This value drops to 0.95 $\mu g/m^3$ and 0.83 $\mu g/m^3$ in the Medium and Low Development Scenarios, respectively.

The maximum annual NO_2 contribution due to all new O&G and mining on Federal lands within the 13 Colorado BLM Planning Areas combined (i.e., Source Group X) for the High, Low and Medium Development Scenarios are, respectively, 0.54, 0.06 and 0.47 $\mu g/m^3$ at Mesa Verde National Park, which represents 22%, 3% and 19% of the NO_2 PSD Class I increment and is primarily due to Federal O&G emissions from the White River FO Planning Area as discussed above. The corresponding estimates using Brute-Force approach (X1) are 0.59 (24%), 0.07 (3%), 0.51 (21%) $\mu g/m^3$, slightly above the CAMx source apportionment estimtes.

For the Combined Source Group that represents all new O&G on both Federal and non-Federal lands and mining within the 13 CO BLM Planning Areas (Source Group A3, approximate as it also includes new non-fed FFO), the maximum NO_2 contribution are 0.64, 0.1 and 0.56 $\mu g/m^3$ for the High, Low and Medium Development Scenarios, respectively, which are all well below the annual NO_2 PSD Class I Increment (2.5 $\mu g/m^3$). The maximum contribution from Source Group A3 to annual NO_2 at any sensitive Class II area in all scenarios is at the Aztec Ruins Class II area: 1.28 $\mu g/m^3$ for the High Scenario, 0.62 $\mu g/m^3$ in the Low Scenario and 0.93 $\mu g/m^3$ in the Medium Development Scenario, all of which are below the Class II area annual NO_2 PSD Increment.

The contributions of the defined coal and oil/gas EGU source groups are all below the annual PSD Class I and Class II Increments.

Table 5-1. Maximum annual NO_2 concentration at any Class I or sensitive Class II area due to the different Source Groups for the 2025 High Development Scenario.

5.1.1.2 SO_2 PSD Concentrations

Tables 5-2 through 5-4 presents the comparison of the maximum annual, 24-hour and 3-hour SO_2 concentrations, respectively, at Class I/II areas with the PSD SO_2 increments for the 35 Source Groups. Note that the Colorado portion of the Dinosaur National Monument is Class I for SO_2 only, so it is included in the Class I area grouping in these tables. Note that PSD Increments are not applicable for Natural or Total emissions or for cumulative EGU emissions in the modeling domain. None of the rest Source Groups exceed the annual, 24-hour and 3-hour PSD Class I Increment at any Class I/II area in any of the scenarios. The contributions of the 14 BLM Planning Areas to SO_2 concentrations at Class I/II areas are extremely small, mostly much less than 1% of the PSD Increments, except for the Federal O&G from the White River Field Office (WRFO) Planning Area, which has by far the largest contribution to annual, 24-hour and 3-hour SO_2 concentrations at any Class I area. The maximum contributions from the White River Field Office (WRFO) Planning Area to the maximum annual, 24-hour and 3-hour SO_2 concentrations for the 2025 High Development Scenario are 3%, 6%, and 3% of the PSD Increment for the High and Medium Development Scenarios (the mitigation in the Medium Development Scenario did not address SO_2 emissions) and less than 1% of the PSD Increment for the Low Development Scenarios, which all occur at the Colorado portion of Dinosaur National Monument.

Table 5-2. Maximum annual SO_2 concentration at any Class I or sensitive Class II area due to the different Source Groups for the 2025 High Development Scenario.

5.1.1.3 $PM_{2.5}$ PSD Concentrations

Tables 5-5 and 5-6 display the maximum annual and 24-hour $PM_{2.5}$ concentrations due the Source Groups at any Class I and II area and presents a comparison with the PSD $PM_{2.5}$ Increments for the 2025 High, Low and Medium Development Scenarios. $PM_{2.5}$ concentrations due to emissions from Federal O&G within any of the 14 BLM Planning Areas do not come close to exceeding any of the PSD $PM_{2.5}$ Increments. The BLM Planning Area with the largest Federal O&G $PM_{2.5}$ contribution at any Class I area is again the White River FO Planning Area that contributes $PM_{2.5}$ concentrations of 4 and 12 percent for the High, 4 and 10 percent for the Medium and 0.5 and 2 percent for the Low Development Scenarios to the annual and 24-hour $PM_{2.5}$ Class I PSD Increments at the Dinosaur NM Class I area.

The maximum contributions at any Class I area to annual $PM_{2.5}$ due to all Federal O&G and mining in the 13 Colorado BLM Planning Areas (Source Group X and X1 are very similar with the latter being slightly higher) are, respectively, 0.05, 0.04, and 0.006 $\mu g/m^3$ that represents 5%, 4%, and less than 1% of the Class I area increment for the High, Medium and Low Development Scenarios. The maximum contributions at any Class I area to 24-hour $PM_{2.5}$ due to all Federal O&G and mining in the 13 Colorado BLM Planning Areas (Source Group X is slightly higher than X1) are, respectively, 0.2, 0.2, and 0.04 $\mu g/m^3$ for the High, Medium and Low Development Scenarios, representing 11%, 9%, and 2% of the Class I area increment.

Extremely high maximum annual and 24-hour $PM_{2.5}$ contributions are seen due to natural wildfire emissions that occurred in 2011 (Source Group A), which are also reflected in the total 2025 (A6) and 2011 (A7) Source Groups for which the PSD Increments are not applicable.

Table 5-5. Maximum Annual $PM_{2.5}$ concentration at any Class I or sensitive Class II area due to the different Source Groups for the 2025 High Development Scenario.

5.1.1.4 PM_{10} PSD Concentrations

The results of the comparisons against the PM_{10} PSD increments is very similar to $PM_{2.5}$ with none of the Source Groups, except Natural Emissions (Source Group A) that are also included in the total 2025 and 2011 Source Groups, showing any exceedances of the annual or 24-hour PM_{10} PSD increment (Tables 5-7 and 5-8). Wildfires within the Natural Emissions Source Group can produce very high PM concentrations.

Of the BLM Planning Areas, Federal O&G from the White River FO has the largest annual and 24-hour PM_{10} concentrations at any Class I area with maximum values that of 1.5% and 4% for the High, 1% and 3% for the Medium Development Scenarios as a fraction of the PSD PM_{10} increment. For the Low Development Scenario, New Mexico Farmington FO (NMFFO) has the largest annual and 24-hour PM_{10} at any Class I area with maximum values of 0.3% and 1% of the PSD PM_{10} increment. The combined Source Groups, i.e., X, X1, A1-A3 PM_{10} impacts at any Class I area are 18% or less of the PM_{10} PSD increments.

5.1.2 PSD Concentration across All Class I and Sensitive Class II Areas

In this section we present examples of the contributions of PSD pollutant concentrations across all PSD Class I and sensitive Class II areas for several of the individual and combined Planning Area Source Groups. The tables below were obtained from the "Summary" sheet of Attachments A-1, A-2 and A-3 Excel spreadsheet that contains results for all of the Source Groups.

5.1.2.1 Individual BLM Planning Area PSD Contributions

All of the PSD pollutant concentrations at Class I areas due to new O&G on Federal lands within each of the 14 BLM other Planning Areas are well below the Class I and II PSD concentration increments. Tables of concentrations contributions at all of the Class I and sensitive Class II areas from each of the 35 Source Groups and the High and Low Development Scenarios can be found in Attachments A-1, A-2 and A-3. Table 5-9 display the contributions of new oil and gas emissions on Federal lands to PSD pollutant concentrations at all Class I and sensitive Class II areas in the CARMMS 12/4 km domain for three BLM Field Office Planning Areas, i.e., White River Field Office (WRFO), Colorado River Valley Field Office (CRVFO), and the RGFO #1 Planning Area.

Table 5-9. Contributions of new oil and gas emissions on Federal lands within the White River Field Office Planning Area (Source Group C) to PSD pollutant concentrations at Class I and sensitive Class II areas for the 2025 High Development Scenario.

Note that the thresholds shown are project-level thresholds. The comparisons shown above are for informational purposes only.

5.1.2.2 Combined BLM Planning Area PSD Contributions

Below we examine the contributions of emissions to concentrations at Class I areas for three of the combination Source Groups: (X) new Federal O&G within the 13 Colorado BLM Planning

Areas; (A2) new Federal O&G and mining within Colorado; and (A3) New federal O&G, new non-federal O&G and mining in Colorado. Results for the other Source Groups as well as results for the sensitive Class II areas are contained in Attachments A-1, A-2 and A-3.

The PSD contributions of Source Group X are below the Class I and Class II PSD increments at all Class I and sensitive Class II areas, respectively, for all PSD pollutants and averaging times and the 2025 High, Low and Medium Scenarios (Table 5-10). As a percentage of a PSD increment, the largest contribution at any Class I area due to Source Group X is 22% (0.54 $\mu g/m^3$), 2% (0.06 $\mu g/m^3$) and 19% (0.47 $\mu g/m^3$) of the 2.5 $\mu g/m^3$ annual NO_2 PSD Class I increment for the High, Low and Medium Development Scenarios, respectively, and occurs at the Dinosaur National Monument. These NO_2 impacts are primarily (92%) due to new Federal O&G emissions from the TRFO Planning Area.

The PSD pollutant concentrations contributions for the 2025 High and Low Development Scenarios are shown in Table 5-11 for Source Group A2 which is the Contributions of new oil and gas and mining on Federal lands within Colorado.

The contributions of new Federal O&G, new non-federal O&G and mining in Colorado (Source Group A3) to PSD pollutants at Class I areas for the three 2025 emission scenarios are shown in Table 5-12. Again, New federal O&G, new non-federal O&G and mining in Colorado produces PSD pollutant concentrations at all Class I and sensitive Class II areas that are all below the PSD Class I and II area increments.

Table 5-10. Contributions of new Federal oil and gas development on Federal lands in Colorado to PSD pollutant concentrations at Class I and sensitive Class II areas (Source Group X) for the 2025 High Development Scenario.

Group	X	Total new federal O&G in CO

5.2 Visibility Impacts at Class I/II Areas using FLAG (2010)

Attachments B-1, B-2 and B-3 are interactive Excel spreadsheets that contain the visibility impacts at Class I and sensitive Class II areas due to emissions from the 35 Source Groups using the FLAG (2010) procedures as described in Section 4.6. There are four interactive sheets in Attachment B:

> "Table1" shows maximum change in (delta) visibility (Δdv), the day of maximum Δdv and number of days that Δdv exceed the 0.5 and 1.0 dv thresholds for all Class I/II areas and a user selected Source Group that is controlled in cell B1.
>
> "Table2" shows the temporal distribution (i.e., maximum and minimum and 98th, 80th and 20th percentiles) of Δdv by user selected Source Group (controlled by cell B1) for all Class I and II areas.
>
> "Table3" shows maximum (or 98th, 80th, 20th or minimum controlled by cell B1) impact of Δdv from all Source Groups across all Class I, all Class II and combined all Class I and II areas.
>
> "Table4" shows the maximum number of days that Δdv is greater than the 0.5 and 1.0 dv thresholds at any Class I or II area for all 32 Source Groups.
>
> "Table 5" shows the number of days that Δdv is greater than the 0.5 and 1.0 dv thresholds and the maximum Δdv at each Class I and sensitive Class II area for a user-selected Source Group controlled by cell B1.

Additional information describing the Attachment B-1 and B-2 spreadsheets are contained in sheets "Readme" and "Ref."

5.2.1 Maximum Visibility Impacts at any Class I Area for all Source Groups

Table 5-13 displays the Class I and II areas where the maximum number of days Δdv exceeds the 0.5 and 1.0 thresholds occurred for each of the Source Groups in the 2025 High Development Scenario. Tables 5-14 and 5-15 show the same information for the 2025 Low and Medium Development Scenarios, respectively. These Tables were obtained from "Table4" in Attachments B-1, B-2 and B-3. The maximum Δdv impact at any Class I and II area due to each the Source Groups for the 2025 High, Low and Medium Development Scenarios are shown in Table 5-16.

Of the 14 BLM Colorado and New Mexico Planning Areas (Source Groups B through O) plus the total CRFO (Source Group Y) and RGFO (Source Group Z) Planning Areas, only WRFO has Federal O&G with Δdv visibility impacts at any Class I area that exceed the 0.5 dv threshold for the 2025 High Development Scenario (Table 5-13). WRFO has 41 days of Δdv > 0.5 and 4 days with Δdv > 1.0 (Table 5-13) and maximum Δdv of 1.555 at Dinosaur Class I Area (Table 5-16).

The individual Source Groups B through O of O&G emissions in BLM Planning Areas have no days with Δdv > 0.5 at any Class I area for the 2025 Low Development Scenario (Table 5-14). The maximum Δdv at any Class I area for Federal O&G within an individual BLM Planning Area

and the 2025 Low Development Scenario is 0.12 from WRFO at Dinosaur Class I Area (Table 5-16a).

Results for the 2025 Medium Development Scenario are similar but lower than the High Development Scenario with WRFO having 32 days with Δdv > 0.5 at any Class I area and 1 day with Δdv > 1.0 at any Class I area (Table 5-15).

When looking at the 2025 High Development Scenario visibility impacts at Sensitive Class II areas, four of the 14 BLM Planning Areas (Source Groups B through O) have maximum Δdv that exceeds the 0.5 threshold: WRFO, GJFO, SUIT and NMFFO (Tables 5-13a and 5-16).

- WRFO with 83 days of Δdv > 0.5 and 25 days with Δdv > 1.0 and maximum Δdv of 2.56 at Dinosaur National Monument.
- GJFO with 6 days of Δdv > 0.5 and 1 days with Δdv > 1.0 and maximum Δdv of 1.23 at Colorado National Monument.
- SUIT with 17 days of Δdv > 0.5 and 1 days with Δdv > 1.0 and maximum Δdv of 1.16 at Aztec Ruins National Monument.
- NMFFO with 261 days of Δdv > 0.5 and 80 days with Δdv > 1.0 and maximum Δdv of 2.66 at Aztec Ruins National Monument.

For the 2025 Low Development Scenario, there are three BLM Planning Areas that have visibility impacts greater than 0.5 dv at any Class II area.

- WRFO has 1 days of Δdv > 0.5 and 0 days with Δdv > 1.0 and a maximum Δdv of 0.51 at Dinosaur National Monument.
- SUIT has 1 days of Δdv > 0.5 and 0 days with Δdv > 1.0 and a maximum Δdv of 0.65 at Aztec Ruins National Monument.
- NMFFO has 82 days of Δdv > 0.5 and 6 days with Δdv > 1.0 and a maximum Δdv of 1.49 at Aztec Ruins National Monument.

New O&G development on BLM Planning Areas result in exceedances of the 0.5 dv visibility threshold at Class II areas for the 2025 Medium Development Scenario for the same four BLM Planning Areas as seen for the 2025 High Development Scenarios only with lower number of days (Tables 5-15a and 5-16b).

- WRFO with 69 days of Δdv > 0.5 and 21 days with Δdv > 1.0 and maximum Δdv of 2.39 at Dinosaur National Monument.
- GJFO with 4 days of Δdv > 0.5 and 1 days with Δdv > 1.0 and maximum Δdv of 1.06 at Colorado National Monument.

- SUIT with 0 days of Δdv > 0.5 and 0 days with Δdv > 1.0 and maximum Δdv of 0.45 at Aztec Ruins National Monument.

- NMFFO with 84 days of Δdv > 0.5 and 9 days with Δdv > 1.0 and maximum Δdv of 1.55 at Aztec Ruins National Monument.

Not surprisingly, when looking at visibility impacts using the FLAG (2010) approach at Class I/II areas due to O&G emissions across combined BLM Planning Areas there are greater visibility impacts than for any individual BLM Planning Area. The FLMs have developed a Cumulative Visibility approach using the regional haze Worst 20 percent days (W20%) and Best 20 percent days (B20%) regional haze rule metric that is used to assess the visibility impacts for these combined Source Groups that is discussed in Section 5.3. The combined Source Group visibility impacts at Class I/II areas using the FLAG (2010) method in Figures 5-13 through 5-15 are provided for information only.

5.2.2 Individual Planning Area Contributions to Visibility Impairment at Class I and II Areas using FLAG (2010)

In this section, we present the visibility impacts at Class I areas due to Federal O&G in five BLM Planning Areas: WRFO, GJFO, SUIT, NMFFO, CRVFO and the 2025 High, Low and Medium Development Scenarios. The first four BLM Planning Areas were selected because they were the ones that had Δdv impacts of greater than 0.5 at any Class I or II area (see Table 5-16), whereas CRVFO was selected as one of our example Planning Areas. Tables 5-17 through 5-21 display the maximum Δdv and number of days Δdv exceeds the 0.5 and 1.0 thresholds for all Class I areas due to emissions from Federal O&G development within the WRFO, GJFO, SUIT, NMFFO and CRVFO Planning Areas, respectively. These Tables were obtained from sheet "Table1" in Attachments B-1, B-2 and B-3. The visibility results for the 2025 High, Low and Medium Development Scenario and these five BLM Planning Areas are summarized as follows, results for the other Source Groups and for sensitive Class II areas can be found in Attachments B-1, B-2 and B-3:

Federal O&G from the WRFO Planning Area and the 2025 High Development Scenario result in 4 days and 41 days at Dinosaur NM with Δdv > 1.0 and Δdv > 0.5, respectively, and maximum Δdv of 1.56 at this Class I Area (Table 5-17). The mitigation in the 2025 Medium Development Scenario reduces these values to 3 and 32 days with Δdv > 1.0 and Δdv > 0.5, and 0.479 maximum Δdv at Dinosaur NM (Table 5-17b). For the 2025 Low Development Scenario, new Federal O&G from the WRFO Planning Area cause no days with Δdv > 0.5 and maximum Δdv of 0.25 at Dinosaur NM (Table 5-17a).

For the 2025 High, Medium and Low Development Scenarios, there are no days with Δdv > 0.5 at any Class I area due to new Federal O&G emissions within the GJFO Planning area; the maximum Δdv are 0.49, 0.40, and 0.02 for the 2025 High, Medium and Low Development Scenarios, all being found at the Arches National Park (Table 5-18).

There are no days with Δdv > 0.5 at any Class I area due to Federal O&G emissions from SUIT for all three 2025 emission scenarios (Table 5-20). However, as shown in Attachments B-1, B-2 and B-3, there are 17, 0 and 0 days with Δdv > 0.5 and 1, 0 and 0 days with Δdv > 1.0 at the Aztec Ruins sensitive Class II area for the 2025 High, Low and Medium Development Scenarios, respectively.

There are no days with Δdv > 0.5 at any Class I area due to Federal O&G emissions from the NMFFO Mancos Shale Development area for all three 2025 emission scenarios (Table 5-20). However, as shown in Attachments B-1, B-2 and B-3, there are 261, 84 and 82 days with Δdv > 0.5 and 80, 9 and 6 days with Δdv > 1.0 at the Aztec Ruins sensitive Class II area for the 2025 High, Low and Medium Development Scenarios, respectively.

New Federal O&G from the CRVFO Planning Area has no days with Δdv > 0.5 at any Class I area for all three 2025 emissions scenarios (Table 5-21). The maximum Δdv impact due to new Federal O&G development in the CRVFO Planning Area is 0.06, 0.05 and 0.05 at Eagles Nest Wilderness for the 2025 High, Low and Medium Development Scenarios, respectively (Table 5-21).

Table 5-17. Maximum Δdv and number of days Δdv exceeds 0.5 and 1.0 for each Class I area due to emissions from Federal O&G within the WRFO Planning Area (2025 High Development Scenario).

5.3 Cumulative Visibility Impacts at Class I Areas

The visibility impacts due to new oil and gas emissions from combined BLM Planning Areas were examined following the procedures provided by the FWS and NPS (FWS and NPS, 2012) and described in Section 4.6.2. These procedures use EPA's Modeled Attainment Test Software (MATS) to project current year observed visibility impairment for the observed best 20 percent (B20%) and worst 20 percent (W20%) visibility days to the future year using the CAMx 2011 Base Case and 2025 High, Low and Medium Development Scenarios modeling results with and without emissions from each of the combined emission Source Groups. The cumulative visibility analysis was conducted for the following four combined Source Groups:

Source Group X: Total new O&G on Federal lands in BLM planning areas in CO, by CAMx source apportionment modeling;

Source Group X1: Total new O&G on Federal lands in BLM planning areas in CO, by the Brute-Force "zero-out" approach.

Source Group A2: New federal O&G and new Mining in CO;

Source Group A3: New federal and non-federal O&G and new Mining in CO;

Attachments C-1, C-2 and C-3 contain the 2011 observed and 2025 projected visibility for the W20% and B20% days at Class I and sensitive Class II areas for the High, Low and Medium

Development Scenarios, respectively, with and without each of the combined Source Groups. Tables 5-22 through 5-27 from Attachments C-1, C-2 and C-3 display the cumulative visibility results at Class I areas for the 2025 High, Low and Medium Development Scenarios, the four combined emission Source Groups listed above and the W20% and B20% days. MATS uses observed PM species concentrations and monthly average relative humidity from IMPROVE monitoring sites to calculate daily visibility impairment from which the W20% and B20% visibility days metrics are determined. Not all Class I areas have a co-located IMPROVE monitoring site. Thus, IMPROVE observations were mapped to nearby Class I areas that did not include an IMPROVE monitor. In Tables 5-22 through 5-27, the Class I area of interest is shown in the first column and the IMPROVE site used to represent observed visibility at the Class I area is shown in the third column. For example, the IMPROVE data from Canyonlands National Park was used to represent observed visibility for both the Canyonlands and Arches National Parks. The MATS includes the IMPROVE site to Class I area mappings. However, MATS does not include mappings between IMPROVE sites and sensitive Class II areas. Thus, we assigned an IMPROVE monitoring site to each sensitive Class II area based mainly on proximity so that MATS could calculate cumulative visibility impacts for the W20%/B20% days at sensitive Class II areas. Tables 5-22 through 5-26 include cumulative visibility impacts for just the Class I areas, the results for the sensitive Class II areas are included in Attachments C-1, C-2 and C-3.

Table 5-22 displays the observed W20% visibility metric for the current year (2011) and the projected W20% metric for the 2025 High Development Scenario with and without each of the four combined Source Groups with differences in the W20% visibility metric shown in Table 5-22a. Source Groups A1, A4 are also included in these tables as well as in Attachments C-1, C-2 and C-3, although our discussions are focused on X, X1, A2, and A3.

From the 2011 current year to the 2025 High Development Scenario future year, the W20% visibility metric is estimated to improve at 22 and degrade at 4 of the 26 Class I areas. The biggest improvement in W20% visibility between 2011 and 2025 High Scenario is a reduction of 0.68 dv that occurs both at Canyonlands National Park and Petrified Forest National Park, where visibility goes from 11.92 dv in 2011 to 11.24 dv in the 2025 High Development Scenario. The two Class I areas with degradation are Capitol Reef National Park (0.03 dv increase), Rocky Mountain National Park (0.09 dv increase), Salt Creek (0.11 dv increase), and White Mountain Wilderness (0.03 dv increase).

There are even more improvements in the W20% visibility between 2011 and 2025 for the Low Development Scenario (Table 5-23). Again the Class I area with the biggest improvement between 2011 and 2025 Low Scenario is a reduction of 0.68 dv at Canyonlands National Park and Petrified Forest National Park. 24 of the 26 Class I areas see W20% visibility improvements between 2011 and 2025 Low Scenario with Capitol Reef National Park and Salt Creek showing W20% visibility degradation by 0.03 dv and 0.11 dv, respectively. The results for the 2025 Medium Development Scenario are similar to the High Development Scenario, with 22 of 26 Class I areas showing improvements in the W20% visibility metric with the largest improvement (0.68 dv decrease) at Canyonlands National Park and Petrified Forest National Park (Table 5-24).

The Source Group X (new Federal O&G in Colorado) contribution to 2025 W20% visibility ranges from a minimum of zero to maximums of 0.24 dv (High), 0.04 dv (Low) and 0.20 dv (Medium) dv

(Tables 5-22a, 5-23a and 5-24a). The largest contribution of X occurs at the Arches National Park for all three Development Scenarios. The Source Group X1 shows same or slightly lower contribution using the Brute-Force approach. The biggest difference is seen in the Arches National Park, where X1 is lower than X by 0.11 dv.

The contributions from New federal O&G and new Mining in CO combined (Source Group A2) are slightly higher than Source Group X, as expected, by including impact from Mining. The Source Group A2 has contributions to 2025 W20% visibility ranging from 0 to maximums of 0.25, 0.06, and 0.21 dv (Medium), respectively, all of which are found at Arches National Park. The contributions of New federal and non-federal O&G and new Mining in CO (Source Group A3) increase further when non-federal O&G contribution is included, with contributions to 2025 W20% visibility ranging from 0 to maximums of 0.50 dv, 0.18 dv and 0.49 dv for the High, Low and Medium Development Scenarios, respectively, all of which are seen at Rocky Mountain National Park.

The results for the B20% visibility days and High, Low and Medium Development Scenarios are shown in Tables 5-25 through 5-27. Between 2011 and 2025 the B20% visibility improves for all but one Class I areas for all three 2025 emission scenarios. The only one Class I area with degraded visibility is Salt Creek, where reduction of 0.01 dv of visibility is seen for all three emission scenarios. The largest improvement in B20% visibility for the High, Low and Medium Development Scenarios are 0.46, 0.47 and 0.46 dv, respectively, all found at Canyonlands National Park and Pecos Wilderness. The Source Groups' X, X1, A2 and A3 contributions to the B20% visibility range from zero to 0.05, 0.04, 0.08, 0.10 dv for the High Development Scenario, zero to 0.01, 0.01, 0.04, and 0.05 dv with the 2025 Low Development Scenario, and zero to 0.04, 0.0.03, 0.07 and 0.09 dv for the Medium Development Scenario, respectively.

Table 5-22. Cumulative visibility results for W20% visibility days at Class I areas for current year (2011) and 2025 High Development Scenario using all emissions and without Source Groups X, A1, A2, A3, A4, and X1.

5.4 Sulfur and Nitrogen Deposition at Class I and Sensitive Class II Areas

Attachments D-1, D-2 and D-3 are interactive Excel spreadsheets that display Maximum and Average sulfur and nitrogen deposition due to emissions from each of the 34 Source Groups shown in Table 4-1 and Table 4-2. As for the PSD concentrations Attachment A spreadsheet, there is a "Summary" sheet that displays the sulfur and nitrogen deposition across all Class I and sensitive Class II areas for a user selected Source Group that is controlled by a drop down menu in cell B5. And a "MaxImpact" sheet that gives the highest sulfur or nitrogen deposition that occurred at any Class I area or sensitive Class II area that is controlled by cell B3 to select Sulfur or Nitrogen and cell B4 to select either Maximum or Average. Here Maximum represents the maximum deposition in any grid cell covering the Class I/II area, whereas Average provides the average of deposition across all grid cells covering a Class I/II area. Although the convention in the past has been to report the Maximum deposition in any receptor in a Class I/II area, since deposition relates to the total amount deposited across an entire watershed, the Average metric is probably a more relevant parameter for evaluating potential environment effects. Both Maximum and Average deposition metrics are reported.

For the deposition impacts associated with Federal O&G within each of the individual BLM Planning Areas (i.e., Source Groups B through O), the sulfur and nitrogen deposition amounts are compared against the 0.005 kg/ha-yr Deposition Analysis Threshold (DAT) for the western United States. The DAT is a screening threshold such that if a Project's deposition amount is below the DAT its deposition impact is considered insignificant. The deposition due to the total emissions, that is Source Groups A6 (2025) and A7 (2011), are compared against the Critical Load Values, which for nitrogen is 2.2 kg/ha-yr in Wyoming and 2.3 kg/ha-yr in Colorado except for 3.0 kg/ha-yr for Dinosaur NM. The Critical Load of atmospheric deposition for sulfur in this analysis is 5.0 kg/ha-yr everywhere.

5.4.1 Highest Deposition Impacts at Class I/II Areas

Tables 5-29 through 5-31 display the highest Maximum and Average nitrogen and sulfur deposition in any Class I or sensitive Class II area due to emissions from each of the 34 Source Groups for the 2025 High, Low and Medium Development Scenarios, respectively. As examples, the results for a number of selected Source Groups, including F (GJFO), J (RGFO #1), X, A4, and X1, are summarized in Tables 5-28 and 5-28a. Note that DATs are Project-level thresholds and thus, Planning Area-level exceedances are less relevant than Project-level exceedances.

5.4.1.1 Individual BLM Planning Area Comparison to DATs

Individual BLM Planning Area (i.e., Source Groups B through O) annual nitrogen and sulfur deposition are compared against the 0.005 kg/ha-yr western U.S. DAT. All deposition flux values reported below have units of kg/ha-yr.

The two BLM Planning Areas with Federal O&G typically having the highest annual nitrogen deposition impact are WRFO with maximum deposition fluxes of 0.135 and average values of 0.075 for the High Scenario, maximum values of 0.119 and average values of 0.065 ad 0.028 for the Medium Scenario, and maximum values of 0.017 and average values of 0.009 for the Low Development Scenario (Tables 5-29 through 5-31).

The annual sulfur deposition from new Federal O&G in the BLM Planning Areas tends to be much lower than seen for the nitrogen deposition, so results for just the 2025 High Development Scenario and maximum sulfur deposition metric are presented in Table 5-32 with the other results provided in Attachments D-1, D-2 and D-3. The only individual BLM Planning Area whose new Federal O&G emissions results in its sulfur deposition exceeding the DAT is the WRFO with a maximum of 0.021 kg/ha-yr in the High Development Scenario. The maximum (0.020 kg/ha-yr) and average (0.014 kg/ha-yr) sulfur deposition due to WRFO for the 2025 Medium Development Scenario are also above the DAT. However, the highest WRFO sulfur deposition for the maximum (0.003 kg/ha-yr) and average (0.002 kg/ha-yr) values in the 2025 Low Development Scenario are below the DAT. The sulfur deposition results for all the other individual BLM Planning areas are below the DAT.

Table 5-28. Highest average nitrogen deposition (kg/ha-yr) at any Class I or sensitive Class II area due to selected Source Groups, including F (GJFO), J (RGFO #1), X, A4, and X1 for the 2025 High, Low and Medium Development Scenarios.

5.4.1.2 Comparisons Against Critical Loads

In this section we compare the total sulfur and nitrogen deposition from all sources in the 2011 Base Case and 2025 High, Low and Medium Development Scenarios with Critical Loads of atmospheric deposition. It is unclear what the sulfur and nitrogen for the combined Source Groups (P-X1) should be compared against given that the DAT and Critical Load LOCs were designed for single Projects and total emissions, respectively. The total nitrogen and sulfur deposition amounts for the combined Source Groups P through X1 are much lower than the Critical Load values (Attachments D-1, D-2 and D-3).

Tables 5-33 and 5-34 display the total nitrogen and sulfur deposition, respectively, at Class I areas for the 2025 High, Low and Medium Development Scenarios, the 2011 Base Case, the differences between the three 2025 scenarios and the 2011 Base Case (2025 minus 2011) and the difference between the three 2025 scenarios and the natural emissions (Source Group A). As seen in Table 5-29, the Class I area with the highest Maximum nitrogen deposition (due to all sources combined) in the 2025 High Development Scenario is the Bandelier Class I area in New

Mexico with a value of 7.05 kg/ha-yr that is over 3 times the nitrogen Critical Load (2.3 kg/ha-yr). However, most (6.44 position kg/ha-yr) of this is due to natural emissions (Source Group A in Table 5-29) and when natural emission contributions are removed the value at Bandelier for the 2025 scenarios (1.60-1.61 kg/ha-yr) drops below the nitrogen Critical Load (2.3 kg/ha-yr) (Table 5-33). After removing natural emission contributions the Maximum nitrogen deposition exceeds the 2.3 kg/ha-yr Critical Load at 6, 6, and 4 of the 26 Class I areas with the highest value of 2.96, 2.73 and 2.93 kg/ha-yr at the Mount Zirkel Wilderness Area and the 2025 High, Low and Medium Development Scenarios, respectively. When examining the Average annual nitrogen deposition across Class I areas, 2, 1, and 2 of the Class I areas exceed the 2.3 kg/ha-yr nitrogen Critical Load for the 2025 High, Low and Medium emission scenarios, respectively.

With no exception, all 26 Class I areas exhibit a reduction in annual nitrogen deposition from 2011 to 2025 with the largest reduction occurring at Mount Zirkel Wilderness (-0.67, -0.90 and 0.70 kg/ha-yr for 2025 High, Low and Medium emission scenarios, respectively) and the second largest reduction occurring at Mesa Verde NP (-0.66, -0.73, and -0.70 kg/ha-yr for 2025 High, Low and Medium emission scenarios, respectively).

The total sulfur deposition at all of the Class I areas for the 2011 and three 2025 emission scenarios are all well below the sulfur Critical Load of 5 kg/ha-yr (Table 5-34). Sulfur deposition is reduced by 10% to 65% across the Class I areas between the 2011 and 2025 High emissions scenarios. The highest sulfur deposition at any Class I area for the three 2025 emission scenarios is 1.32 kg/ha-yr at Gila Wilderness that is approximately a factor of 4 below the sulfur deposition Critical Load (5.0 kg/ha-yr) (Table 5-34).

Additional results, including those for sensitive Class II areas and all Source Groups, are found in Attachments D-1, D-2 and D-3.

Table 5-33. Total annual nitrogen deposition at Class I areas for the 2025 High Development Scenario, 2011 Base Case, their differences (2025 High minus 2011) and 2025 High Development Scenario without the contributions of natural emissions (e.g., wildfires).

5.5 Acid Neutralizing Capacity (ANC) at Sensitive Lakes

Acid Neutralizing Capacity (ANC) at sensitive lakes was calculated for each Source Group following the procedures given in Section 4.8. For a Project, the USFS ANC Level of Acceptable Change (LAC) threshold is no change greater than 10% for lakes with base ANC > 25 µeq/l and no change greater than 1 µeq/l for lakes with base ANC values < 25 µeq/l. Attachments E-1, E-2 and E-3 are interactive Excel spreadsheet that displays the change in ANC at the sensitive lakes due to emissions from each of the 34 Source Groups and the High, Low and Medium Development Scenarios, respectively. The Source Group to be displayed is controlled by cell B3 with the resultant change in ANC (Delta ANC) shown as a percent in Column N and as µeq/l in Column O with an indication of whether it is below the USFS LAC value given in Column P. Although ANC is presented for each Source Group, the ANC results for the Source Groups with existing sources are not meaningful since their effects are contained within both the 10 percentile baseline lake acidity as well as the incremental acidity added to the baseline.

5.5.1 ANC Calculations for Individual BLM Planning Areas

For new Federal O&G from each of the 14 BLM Planning Areas (Source Groups B through O) the change in ANC were below the USFS LAC significance thresholds at all of the sensitive lakes. For example, Table 5-35 displays ANC results from Attachment E-1 (2025 High Development Scenario) for the WRFO, CRVFO, GJFO, RGFO #1 Planning Areas (Source Groups C, D, F, and J). Note that Attachment D contains more information on the sensitive lakes than presented in Table 5-35 including the lake chemistry parameters. For new Federal O&G from the WRFO Planning Area and the 2025 High Scenario, the maximum change in ANC at any sensitive lake is 6.5% at the Upper Ned Wilson Lake in the White River National Forest. This change is below both of the USFS LAC values (Table 5-35). For new Federal O&G within the CRVFO Planning Area and the 2025 High Scenario, the maximum change in ANC at any sensitive lake is 0.88% at the Upper Ned Wilson Lake in the White River National Forest, which is below the USFS LAC thresholds (Table 5-35a). New Federal O&G development within the GJFO results in ANC impacts that are all below the threshold in the High Development Scenario with the maximum ANC change of 2.58% at the Upper Ned Wilson Lake in the White River National Forest. New Federal O&G development within the RGFO #1 Planning Area has almost no effect on acidification at the sensitive lakes with maximum change in ANC values of 0.03% (Table 5-35b). ANC results for the other BLM Planning Areas and the 2025 Low and Medium Development Scenario are contained in Attachments E-1, E-2 and E-3.

Table 5-35. ANC calculations at sensitive lakes for new Federal oil and gas development within the BLM White River Field Office Planning Area (Source Group C) and the 2025 High Development Scenario.

Note that the thresholds shown are project-level thresholds. The comparisons shown above are for informational purposes only.

5.5.2 ANC Calculations for Combined BLM Planning Areas

The Attachment E-1, E-2 and E-3 spreadsheets also contain ANC calculations for the combined BLM Planning Area Source Groups P through X1 of new emission sources. Below we provide results for new Federal oil and gas development and mining within the 13 Colorado BLM Planning Areas (Source Group A2) and the Source Group A3 that represents new Federal and new non-Federal oil and gas development and mining within the 13 Colorado Planning Areas.

Table 5-36 displays the ANC results at the 58 sensitive lakes for the combined new Federal O&G and mining within the 13 Colorado BLM Planning Areas (Source Group A2) and the 2025 High, Low and Medium Development Scenarios. For all the lakes, the maximum percent change in ANC is always below the USFS LAC 10% threshold for all three 2025 emission scenarios.

The ANC results for new Federal and new non-Federal oil and gas development and mining within the 13 Colorado Planning Areas (Source Group A3) and the 2025 High, Low and Medium Emissions Scenario are shown in Tables 5-37 and 5-38. For the lakes that have base ANC values > 25 µeq/l the maximum percent change in ANC is always below the USFS LAC 10% threshold for all three 2025 emission scenarios. However, for the 3 lakes with base ANC < 25 µeq/l, three have changes in ANC greater than the 1 µeq/l USFS LAC threshold for the 2025 High Development Scenario (Table 5-37): Upper Ned Wilson Lake (1.1 µeq/l); Blue Lake (1.2 µeq/l) and Deep Creek Lake (3.4 µeq/l). The mitigation in the 2025 Medium Development scenario is not sufficient to reduce the change in ANC value at the three lakes to below the 1 µeq/l LAC threshold. Upper Ned Wilson (1.03 µeq/l), Blue Lake (1.2 µeq/l) and Deep Creek (3.3 µeq/l) remain above the LAC threshold (Table 5-38). For these same three lakes the change in ANC values are all below the 1 µeq/l USFS LAC threshold for the 2025 Low Development Scenario (Table 5-38).

Note that the USFS ANC LAC thresholds were developed for evaluating potential lake acidification for individual Projects, not for quasi-cumulative emission source groups of new O&G development across an entire state as in Source Groups A2 and A3. In addition, the USFS ANC LAC thresholds were developed for evaluating potential lake acidification for individual Projects (i.e. new emissions since baseline lake chemistry data was monitored), not for cumulative emissions scenarios that include all existing O&G since the baseline ANC values that are used in the ANC calculations would already account for impacts from existing emissions sources.

Table 5-36. ANC calculations at sensitive lakes for new Federal oil and gas development and mining within the 13 Colorado BLM Planning Areas (Source Group A2) and 2025 High Development Scenario.

Lake	National Forest	Wilderness Area	State	Latitude (Deg N)	Longitude (Deg W)	Elevation (m)	10th Percentile Lowest ANC Value (μeq/L)	Total S Dep (kg-S/ha-yr)	Total N Dep (kg-N/ha-yr)	PPT (m)	Delta ANC (%)*	Delta ANC (μeq/L)*	USFS LAC Threshold	Below Threshold?	2025 Hi Predicted 10th Percentile Lowest ANC Value (μeq/L)

5.6 2025 NAAQS Comparisons

In this section we compare the CAMx 2025 High, Low and Medium Development Scenario modeling results with the National Ambient Air Quality Standard (NAAQS). For the ozone NAAQS analysis, the results are analyzed using both the absolute CAMx 2025 modeling results as well as using the CAMx 2011 and 2025 modeling results in a relative fashion to scale the observed DVB to project future year 2025 DVF as recommended by EPA (2007) and described in Section 4.5.

5.6.1 Ozone NAAQS Analysis using Relative Modeling Results

EPA's Model Attainment Test Software (MATS) was used to make future year ozone DVF projections using the CAMx 2011 Base Case and 2025 High and Low Development Scenario modeling results. MATS was also used to make ozone DVF projections for the 2025 High and Low Development Scenario removing the contributions of six of the combined Source Groups X, A1, A2, A3, A4, and X1. MATS was used to make 2025 ozone DVF projections at the monitoring sites as well as throughout the CARMMS modeling domain using the MATS Unmonitored Area Analysis (UAA) procedures.

5.6.1.1 Ozone Design Value Projections at Monitoring Sites

The results of the 2025 ozone DVF projections at the monitoring sites are given in Attachments F-1, F-2 and F-3 and shown in Table 5-39. The maximum DVB (based on 2009-2013 observations) is 80.7 ppb at the CO_Douglas_0004 monitor in Douglas, CO, which is projected to be reduced to 74.5, 73.5 and 74.4 ppb for the 2025 High, Low and Medium Development Scenarios, respectively. There are 26 (out of 55) monitoring sites in the CARMMS 12/4 km domain with DVB above the ozone NAAQS (i.e., DVB ≥ 71 ppb). We note that 71 ppb is used for comparison rather than 70 ppb because EPA recommends rounding 8-hr ozone design values to the tenths digit until the last step in the MATS calculation when the final base or future design value is truncated to the nearest ppb. We also note that the ozone NAAQS is based on a 3-year average while the DVB is based on a 5-year observational period. Because DVBs are available here from the MATS analysis, they are compared to the NAAQS as they provide a measure of the severity of ozone concentrations in the base time period (here 2009-2013). The number of sites with DVF above the NAAQS is reduced to8, 6, and 8 in the 2025 High, Low, and Medium emission scenarios, respectively. Removing the contributions due to new O&G (Source Group X) or new O&G and mining (Source Group A2) on Federal lands within the 13 Colorado BLM Planning Areas reduces the 2025 DVF at Douglas, CO to 73.9(or 73.8), 73.4(or 73.3) and 73.9(or 73.9) ppb for the High, Low and Medium Development Scenarios, respectively; all these values are still above the ozone NAAQS (71.0 ppb or higher). When emissions from new non-Federal O&G within the 13 Colorado Planning Areas are also removed (Source Group A3), the projected 2025 DVFs at Douglas, CO are 72.1, 72.6 and 72.2 ppb for the High, Low and Medium Development Scenarios, all still above the NAAQS. The maximum reduction in 2025 DVFs due to the removal of Source Group X at any monitor is 3.0 ppb at Garfield, CO (CO_Garfield_0012) in the High Development Scenario. The corresponding maximum reductions by removing Source Group X in the Low and Medium Scenarios are 1.2 and 2.6 ppb, respectively. The maximum reduction in 2025 DVF due to the removal of Source Group X, X1, A2, A3 in the High Development Scenario are, respectively, 3.3, 2.2, 3.4, and 7.2 ppb at the Garfield

(CO_Garfield_0012) monitoring site. Compared to the results with Source Group X, removing X1 (equivalent to X but with Brute-Force approach) shows slightly less reduction of DVF.

Table 5-39. Current year ozone Base Design Values (DVB) and projected 2025 future year ozone Design Values (DVF) for the 2025 High Development Scenario and without Source Group X, X1, A1, A2, A3 and A4.

5.6.1.2 Ozone Design Value Projection Unmonitored Area Analysis

MATS was used to perform an unmonitored area analysis (UAA) of the 2025 ozone DVF projections for the 2025 High, Low and Medium Development Scenarios and the 2025 results without the contributions from the combined Source Groups X, X1, A1, A2, A3, and A4. The MATS UAA interpolates the current year observed ozone DVBs across the CARMMS 12/4 km domain and then makes 2025 ozone DVF projections throughout the domain using the relative change in the CAMx 2011 and 2025 modeling results in each 12/4 km grid cell. Figure 5-1 displays the spatial distribution of the MATS UAA derived 2011 ozone DVBs and 2025 ozone DVFs and their differences for the three 2025 emission scenarios. The color scheme for the spatial plots has a cut-point at 71.0 ppb so tiles that are yellow or warmer indicate exceedances of the 0.070 ppm ozone NAAQS.

The current year DVBs indicate areas of ozone exceedances in and around Denver, places in Utah, Arizona, New Mexico, and Texas, with a maximum DVB of 109.6 ppb next to the AZ/NM boarder that is found to be caused by wild fire emissions (Figure 5-1, top left). For the 2025 High, Low and Medium Development Scenarios the areas of 2025 ozone DVF exceedances are substantially reduced, while the natural wild fire emissions lead to 108.8 ppb of maximum DVF for all three scenarios near the AZ/NM boarder (top right in Figures 5-1a, 5-1b and 5-1c). The 2025 DVF – 2011 DVB difference plots (Figure 5-1, bottom) shows largest ozone reductions with the largest reduction in the Denver metropolitan area.

The 2025 UAA ozone DVF without Source Group A2 (Federal O&G and mining in 13 CO BLM Planning Areas) results in reduction in the DVFs in northern and northeastern CO, with the highest reductions of 3.4, 1.5, 2.9 ppb in the CRVFO Planning Area in the County of Garfield (Figure 5-2a, top panels) in the High, Low and Medium Development Scenarios. The areas exceeding the NAAQS do not show notable changes when impact from Federal O&G and mining in CO is excluded.

Removing both Federal O&G and mining and non-Federal O&G (Source Group A3) in CO results in more reductions in the 2025 DVFs, especially in northeastern CO and Weld County in the greater Denver area (Figures 5-2a, 5-3a and 5-4a, bottom panels). The largest reductions are 7.3 ppb (High Scenario), 3.1 ppb (Low Scenario) and 6.8 ppb (Medium Scenario) in the CRVFO Planning Area in Garfield County.

Figures 5-2b, 5-3b and 5-4b show the 2025 UAA ozone DVF without Source Group X and X1, which represent new Federal O&G in CO with Source Apportionment modeling and Brute Force approach, respectively. Overall, removing X or X1 does not lead to a substantial change in NAAQS ozone exceedance areas, while removing X1 has slightly less impact than removing X. The maximum impact of new Federal O&G in CO is 3.3, 1.4 and 2.8 ppb for the 2025 High, Low and Medium Development Scenarios, respectively, with X, and 2.4, 1.0, and 2.0 ppb, respectively, with X1.

5.6.2 Ozone NAAQS Analysis using the Absolute Modeling Results

The CAMx source apportionment absolute modeling results in the 2025 High, Low and Medium Development Scenarios are analyzed and compared to the NAAQS in this section. The ozone NAAQS is defined as the three-year average of the 4th highest daily maximum 8-hour (DMAX8) ozone concentration. Since CARMMS 2.0 only uses one year of modeling results (2011 meteorological year), the 2025 4th highest DMAX8 ozone concentration is used as a pseudo-NAAQS comparison metric. The contribution of each Source Group to total modeled ozone at each grid cell of the 12/4 km modeling domain is obtained as the ozone concentration from each Source Group at the time when the 4th highest DMAX8 ozone concentration occurred. The contribution of each Source Group to modeled 2025 4th high DMAX8 ozone greater than the NAAQS (i.e., 71.0 ppb or greater) is also analyzed.

5.6.2.1 Contributions of Source Groups to 4th High DMAX8 Ozone

Figure 5-5 displays the 4th highest DMAX8 ozone for the 2011 Base Case and the 2025 High, Low and Medium Development Scenarios and their differences, and the 4th highest DMAX8 ozone for the 2025 scenario with the ozone contributions from natural emissions removed (Source Group A). This last display was generated to determine whether exceedances of the NAAQS could have been primarily due to natural emissions. The color scale in Figure 5-5 has a sharp contrast from green to yellow when an exceedance of the ozone NAAQS occurs (i.e., 71.0 ppb or higher).

For the 2011 Base Case, there are vast regions where the modeled 2025 4th high DMAX8 ozone exceeds the NAAQS (Figure 5-5, top left) in the domain, while natural fires lead to the highest ozone along NM/AZ boarder and near Los Alamos of NM.

In the 2025 High, Low and Medium Development Scenarios, the areas of ozone exceedances decrease from the Base Case. The 2025 – 2011 ozone differences (Figure 5-5, bottom left) show decreases in almost all areas, with largest reductions of -8.3, -9.2, and -8.4 ppb for the High, Low and Medium Scenarios, respectively. The largest increase of ozone of 5.3 ppb is found in the Moffat County of NM in all three scenarios. The contribution of natural emissions to the modeled 4th highest daily maximum 8-hour ozone concentrations (Figure 5-5, bottom right) confirms the extraordinary contribution from natural wild fires, with a maximum contribution at 61.3 ppb.

Attachment I is a zipped file that contains spatial maps of concentrations including total concentrations and the contributions of each of the Source Groups to the 4th highest DMAX8 ozone and other pollutants from the 2025 High, Low and Medium Development Scenarios CAMx source apportionment modeling. Figure 5-6 displays example spatial maps of contributions to the 4th highest DMAX8 ozone concentrations for CRVFO, White River FO, GJFO, RGFO #1, new Federal O&G in CO (Source Group X), new Federal O&G and Mining in CO (Source Group A2), new Federal O&G, new non-Federal O&G, and new mining in Colorado (Source Group A3), new Federal O&G in CO with Brute Force approach (X1) for the 2025 High, Low and Medium Development Scenarios that were extracted out of Attachment I.

The maximum ozone contributions to the 4th highest DMAX8 ozone for each of the Source Groups are given in Table 5-40. Note that these are maximum Source Group contributions to

the 4th highest DMAX8 ozone and could occur when the total ozone is less or greater than the ozone NAAQS. Section 5.6.2.2 discusses the Source Group contributions only when the total 4th high DMAX8 ozone exceeds the ozone NAAQS. Ozone contributions due to Federal O&G development in the White River Field Office Planning Area are centered on the WRFO area where a maximum ozone contribution of 7.1 ppb occurs for the 2025 High Development Scenario (Table 5-40 and Figure 5-6a, top left). The mitigation in the 2025 Medium Development Scenario reduces this maximum GJFO ozone contribution by -7% to 6.5 ppb. There are much lower 4th high DMAX8 ozone contributions due to WRFO in the 2025 Low Development Scenario (Figure 5-6a, top right) with a maximum contribution of only 1.0 ppb.

Lower 4th high DMAX8 ozone contributions are seen for CRVFO new Federal O&G with highest ozone contributions of 0.4, 0.1 and 0.3, ppb respectively, for the 2025 High, Low and Medium Development Scenarios occurring in the northeast corner of the CRVFO Planning Area (Figure 5-6b).

Ozone contributions due to new Federal O&G within the GJFO area have maximum values of 3.8, 0.2, and 3.2 ppb in the 2025 High, Low and Medium Development Scenarios, respectively (Figure 5-6c).

New Federal O&G emissions in the RGFO #1 Planning Area have peak contributions of 0.4, 0.1 and 0.2 ppb respectively, to fourth highest daily maximum 8-hour ozone from in the 2025 High, Low and Medium Development Scenarios.

The maximum ozone contribution due to Federal O&G throughout the 13 CO Planning areas (Source Group X) for the 2025 High, Low and Medium Development Scenarios are, respectively, 8.7, 2.3 and 7.9 ppb and occur in the White River FO (Table 5-40 and Figure 5-6e). The compartments estimated by X1 (Figure 5-6h) are 6.7, 1.6, and 6.0 ppb, respectively.

Contributions to fourth highest daily maximum 8-hour ozone due to emissions from new Federal O&G and Mining in CO (A2) are shown in Figure 5-6f, and are similar to those by Source Group X (without Mining) in Figure 5-6e, with maximum contributions at 8.7, 3.3, and 7.9 ppb for the 2025 High, Low and Medium Scenarios, respectively. The contributions from new Federal O&G and Mining in CO together with new non-Federal O&G are higher, with maximum contributions at 14.2, 4.8, 13.4 ppb, for the 2025 High, Low, and Medium Scenarios, respectively.

Table 5-40. Maximum contribution to the 4th highest DMAX8 ozone (ppb) for each of the Source Groups and the 2025 High, Low and Medium Development Scenarios.

5.6.2.2 Source Group Absolute Contributions to Ozone Exceedances

The contributions of each Source Group to 4th highest DMAX8 ozone above the current ozone NAAQS (71.0 ppb and higher) for the 2025 High, Low and Medium Development Scenarios are contained in Attachments G-1, G-2 and G-3, respectively. The Attachment G interactive Excel spreadsheet contains two sheets: "StatTable" that displays the maximum ozone contribution for each Source Group to modeled 2025 DMAX8 ozone greater than the NAAQS. Table 5-41 from StatTable in Attachment G lists the maximum ozone contribution to any modeled 2025 4th high DMAX8 ozone greater than the NAAQS. The White River FO is the individual BLM Planning Area with the largest contribution to 2025 modeled exceedances of the ozone NAAQS of 1.5 ppb for the High, 0.1 ppb for the Low and 0.8 ppb for the Medium Development Scenarios when the 2025 total ozone was 71.1, 71.2 and 71.1 ppb, respectively.

The highest contribution to 2025 DMAX8 ozone for all Federal O&G and mining within the 13 Colorado BLM Planning Areas (Source Group X) is 4.5, 0.3 and 1.0 ppb for the 2025 High, Low and Medium Development Scenarios, respectively, while the Brute-Force compartments (X1) are 2.9, 0.3, and 0.7 ppb, respectively. The contribution of new Federal and non-Federal O&G and Federal mining within Colorado (Source Group A2) to 2025 DMAX8 ozone exceedances are 4.6, 0.5 and 1.2 ppb for the High, Low and Medium Development Scenarios, respectively.

Figure 5-7 shows the contribution from new Federal O&G in (X) and new Federal O&G and mining in CO (A2) as a function of the 2025 4th high DMAX8 ozone at all grid cells that exceed NAAQS in the domain that came from the "Scatter" sheet in Attachments G-1, G-2 and G-3. This figure shows that the excessive ozone concentrations above NAAQS do not correlate with the contribution of X or A2. As a matter of fact, the cases with highest 4th high DMAX8 are associated with relatively very low contributions from these two source groups. For the 2025 High O&G Development Scenario, for both X and A2, there are only 4 cases when the contribution is much higher than 1 ppb.

Table 5-41. Maximum ozone contribution by Source Group to total modeled 2025 4th high DMAX8 ozone greater than the NAAQS for the 2025 High Development Scenario.

Group	Name	Max		
		Max Contribution (ppb)	Corresponding 4th MDA8	% Max Contribution

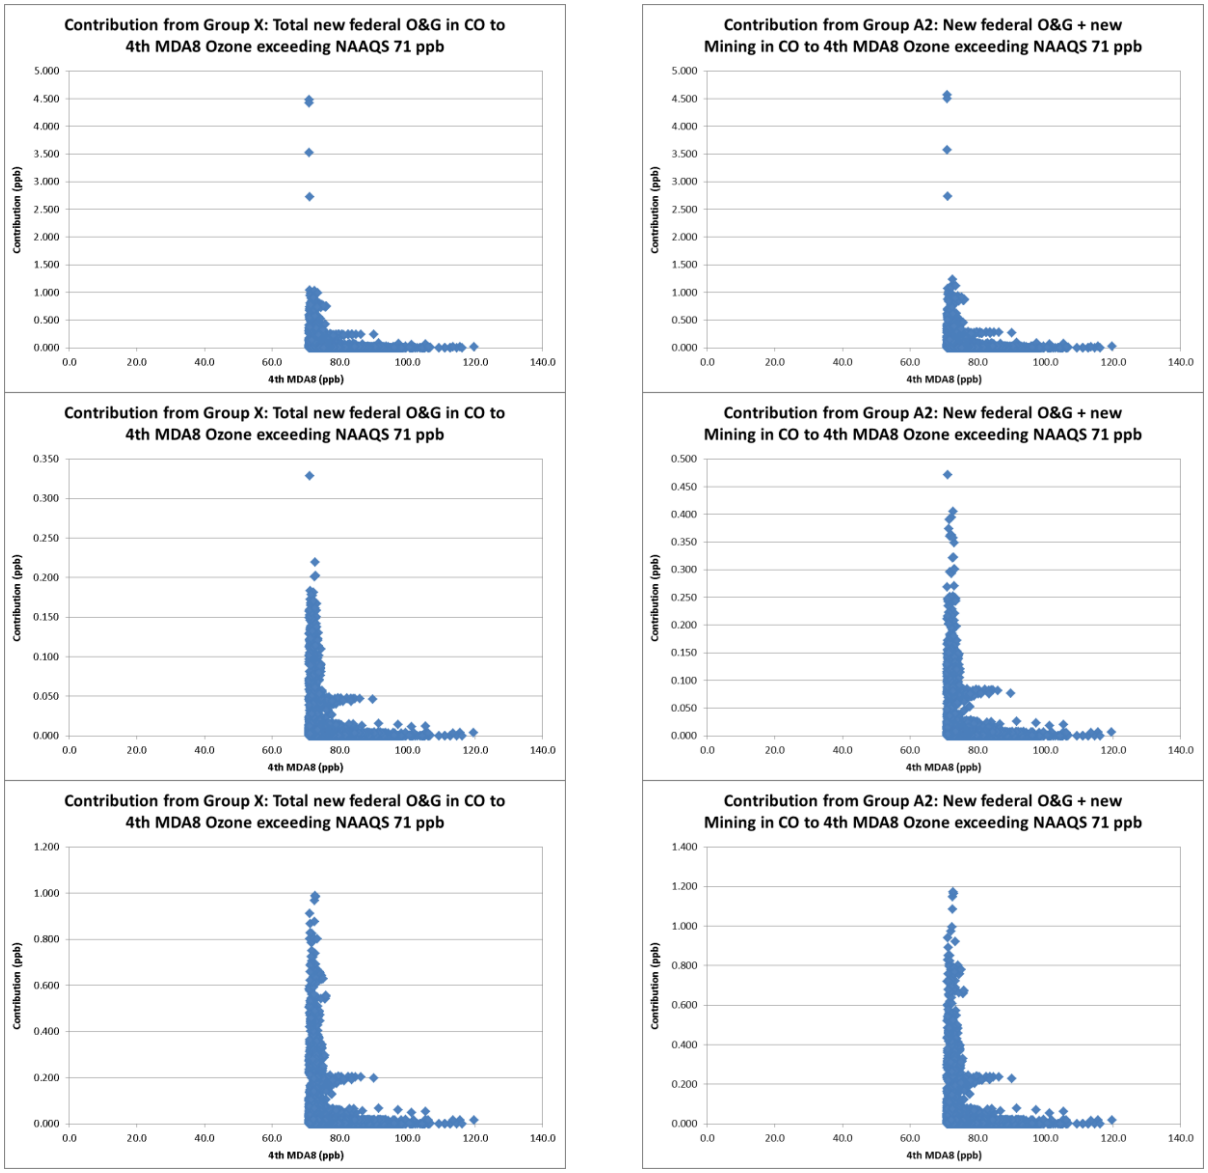

Figure 5-7. Contributions of Federal O&G from new Federal O&G (Source Group X; left) and new Federal O&G and mining in CO (Source Group A2; right) to modeled fourth highest daily maximum 8-hour ozone concentrations greater than the NAAQS for the 2025 High (top), Low (middle) and Medium (bottom) Development Scenarios.

5.6.3 $PM_{2.5}$ NAAQS Analysis

There are two $PM_{2.5}$ NAAQS, one for a 24-hour averaging time that is expressed as a three-year average of the 98th percentile value in a year with a threshold of 35 µg/m^3 and an annual average over three-years with a threshold of 12 µg/m^3. With a complete year of modeling results, the 98th percentile corresponds to the 8th highest daily $PM_{2.5}$ concentration in a year.

5.6.3.1 24-Hour $PM_{2.5}$ NAAQS Analyses

Figure 5-8 displays the 8th highest 24-hour $PM_{2.5}$ concentrations for the 2011 Base Case and 2025 emission scenarios and their differences and the contributions of Natural Emissions to the 8th highest 24-hour $PM_{2.5}$ concentration. The maximum 8th high 24-hour $PM_{2.5}$ in 2011 (421.3 µg/m^3) and 2025 High, Low and Medium Development Scenarios (420.9 µg/m^3) far exceed the 35 µg/m^3 NAAQS (Figure 5-8, top panels). This high value occurs on the AZ/NM boarder and is largely due to emissions from wildfires (406.5 µg/m^3), as shown from the map of contribution by Natural Emissions (Figure 5-8, bottom right). The greater Denver area shows exceedance in 2011 Base case and all three 2025 Scenarios. The maps of difference between 2015 Scenarios and 2011 Base case (Figure 5-8, bottom left) show decrease of $PM_{2.5}$ concentrations in a majority of places in the domain and increase in many places, including Denver, eastern Utah, and central and northwestern New Mexico.

Figures 5-9 through 5-11 show the contribution of new Federal O&G in CO to 8th high 24-hour $PM_{2.5}$ in 2025 High, Low and Medium Scenarios. The maximum contribution is 6.3, 0.9 and 5.6 µg/m^3 for the High, Low and Medium Scenarios, respectively, all of which occur in the White River Field Office Planning Area, while the maximum is found in a different place for the Medium Scenario than the High and Low Scenarios.

Figure 5-12 displays the contributions of Federal O&G from the WRFO (top left), CRVFO (top right), GJFO (bottom left), and RGFO #1 Planning Areas to the 8th highest 24-hour $PM_{2.5}$ concentrations for the 2025 High Development Scenario. Results for the 2025 Low and Medium Development Scenario are lower and can be found in Attachment I. The maximum contribution to 8th highest 24-hour $PM_{2.5}$ concentration due to emissions from new Federal O&G in these four Source Groups in the High Development Scenario are 6.3 µg/m^3 (WRFO), 0.3 µg/m^3 (CRVFO), 2.6 µg/m^3 (GJFO) and 1.3 µg/m^3 (RGFO #1) (Table 5-42).

Figure 5-13a shows the contributions of new Federal O&G and mining in CO (Source Group A2) to $PM_{2.5}$ concentrations in the three 2025 Development Scenarios. The peak 8th highest daily $PM_{2.5}$ concentrations are 6.3, 4.2 and 5.6 µg/m^3 in the 2025 High, Low and Medium Development Scenarios, respectively. Figure 5-13b presents the contributions of new Federal and non-Federal O&G and mining in CO (Source Group A3) for the 2025 High, Low and Medium Development Scenarios. The peak 8th highest daily $PM_{2.5}$ concentrations are 17.6, 6.1 and 17.5 µg/m^3 in the 2025 High, Low and Medium Development Scenarios, respectively. Comparing Figure 5-13a and Figure 5-13b suggests that these peaks near Denver are to a large extent due to contribution from non-Federal O&G. The year 2025 minus year 2011 impacts difference plots (bottom left of Figures 5-8a, 5-8b and 5-8c) in conjunction with plots for Source Groups A2 and A3 indicate relatively large increases in 24-hour $PM_{2.5}$ concentrations primarily due to new non-Federal oil and gas in the RGFO #1.

Table 5-42 summarizes the maximum contribution to the 8th highest 24-hour $PM_{2.5}$ concentrations for all of the Source Groups and the 2025 High, Low and Medium Development Scenarios. For most BLM Planning Areas, the contribution of Federal O&G to the 8th highest 24-hour $PM_{2.5}$ concentrations is small, around or less than 1 $\mu g/m^3$. The top 6 contributors for the High Development Scenario are White River FO (6.3 $\mu g/m^3$), Southern Ute Indian Tribe (2.9 $\mu g/m^3$), Grand Junction FO (2.6 $\mu g/m^3$), Little Snake FO (1.3 $\mu g/m^3$), RGFO #1 (1.3 $\mu g/m^3$), and RGFO #3 (1.3 $\mu g/m^3$), which are also the largest contributors for the Low and Medium Scenarios.

Table 5-42. Maximum contribution to the 8th high 24-hour $PM_{2.5}$ concentrations ($\mu g/m^3$) for each of the Source Groups and the 2025 High, Low and Medium Development Scenarios.

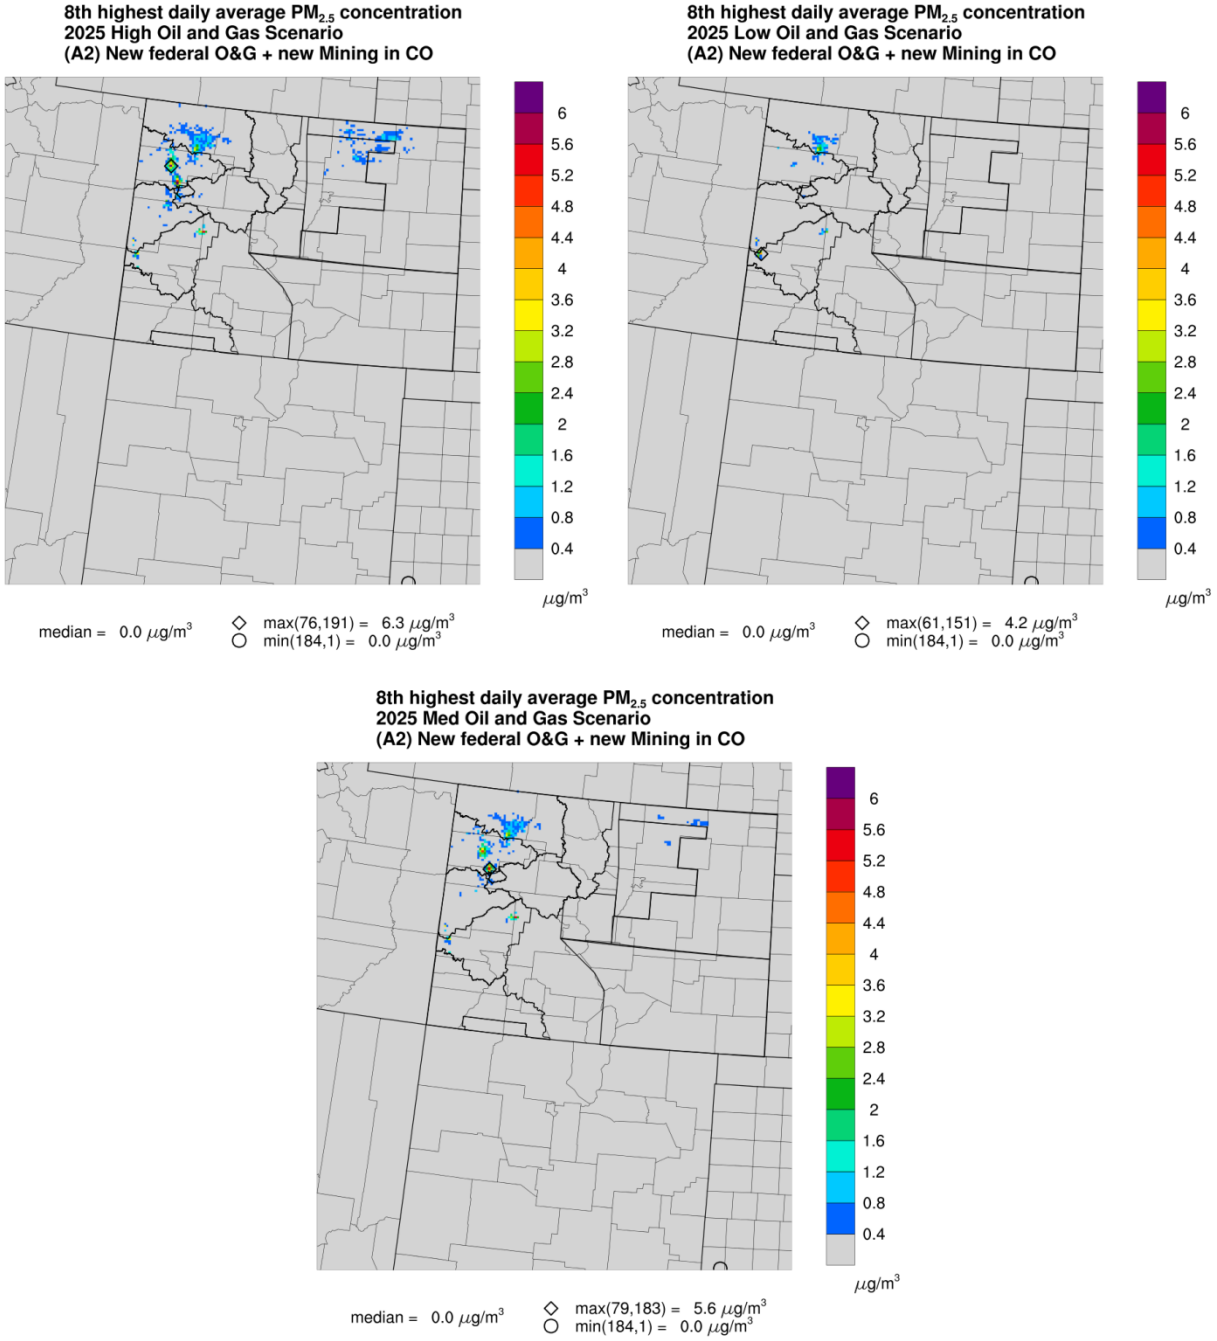

Figure 5-13a. Contribution to 8th highest daily $PM_{2.5}$ concentration from new Federal O&G and mining in CO (source group A2) for the 2025 High (top left), Low (top right) and Medium (bottom) Development Scenarios.

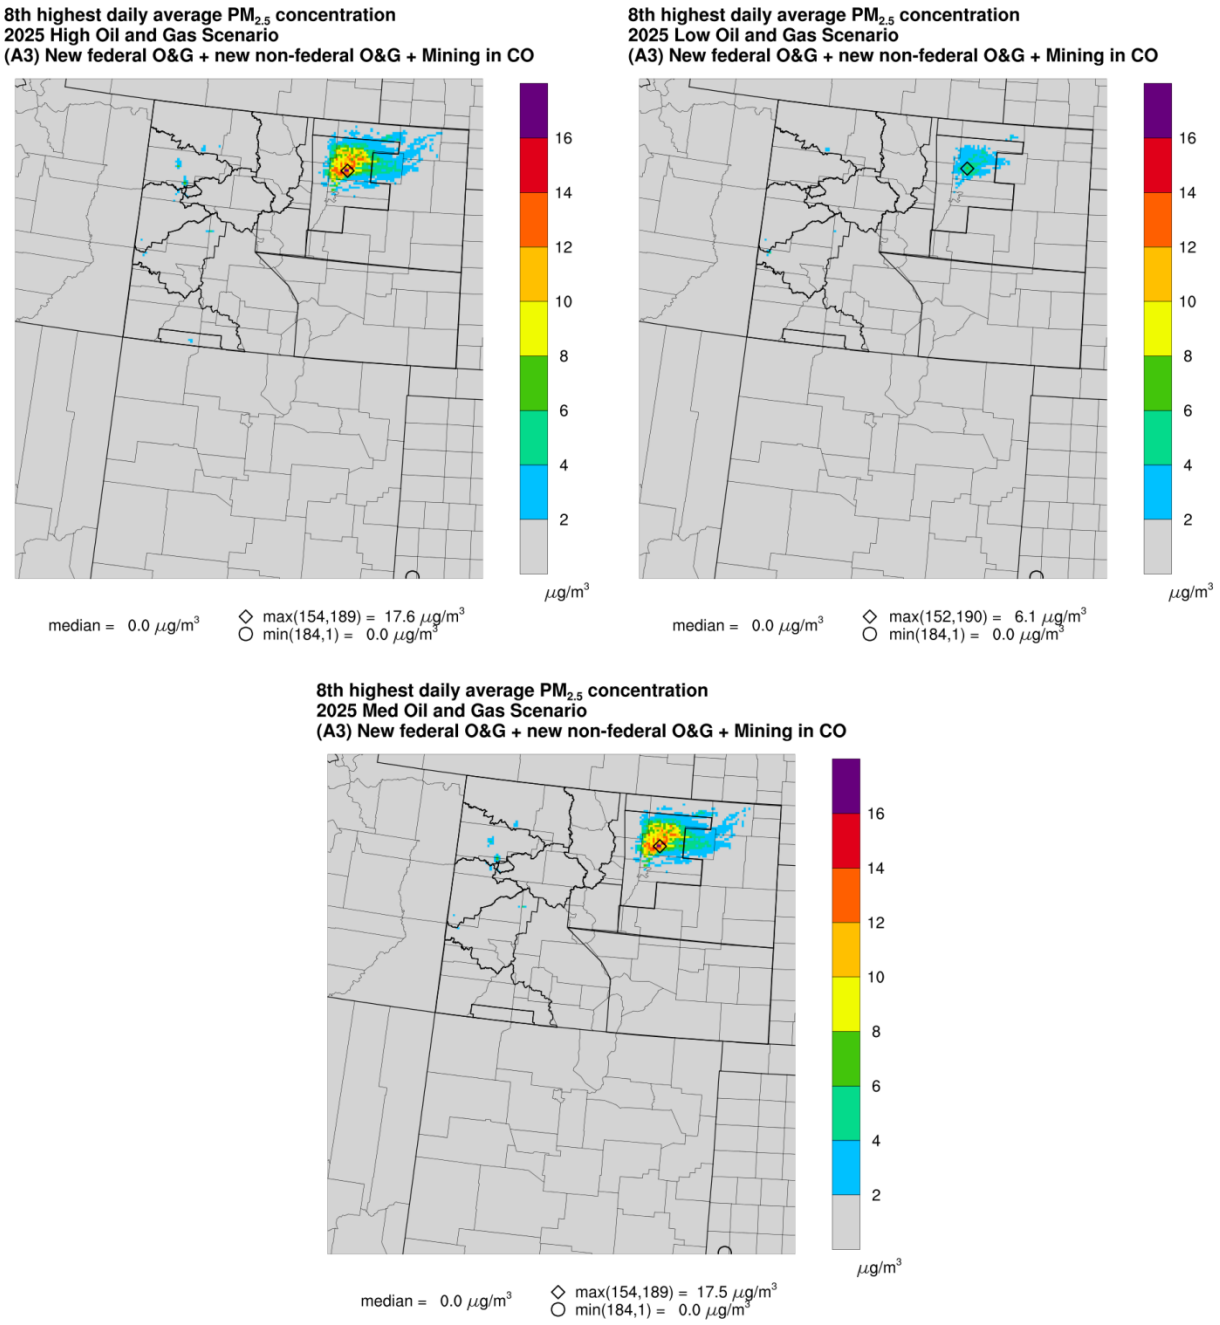

Figure 5-13b. Contribution to 8th highest daily $PM_{2.5}$ concentration from new Federal O&G, new non-Federal O&G, and mining in CO (source group A3) for the 2025 High (top left), Low (top right) and Medium (bottom) Development Scenarios.

5.6.3.2 Annual $PM_{2.5}$ NAAQS Analysis

Figure 5-14 displays the annual average $PM_{2.5}$ concentrations for the 2011 Base Case and 2025 emissions scenarios and their differences and the annual average $PM_{2.5}$ concentrations due to Natural Emissions. The highest annual average $PM_{2.5}$ concentration is about 23.5 μg/m^3 for the 2011 Base Case, and 21.1, 20.9, and 21.0 μg/m^3 in the 2025 High, Low, and Medium Development Scenarios. Compared to the year of 2011, annual $PM_{2.5}$ concentrations drop in the majority of places in the domain, and increases in a number of places, including in the RGFO #1 Planning Area near Denver, where about 10 μg/$m^3$of increase in annual $PM_{2.5}$ occurs for the High and Medium Development Scenarios.

The maximum contribution of each Source Group to annual $PM_{2.5}$ concentrations for the 2025 High and Low Development Scenarios are shown in Table 5-42a. The 6 Planning Areas with highest contributions are White River FO (3.4 μg/m^3), Southern Ute Indian Tribe (1.4 μg/m^3), Grand Junction FO (1.2 μg/m^3), Little Snake FO (0.6 μg/m^3), RGFO #1 (0.6 μg/m^3), and RGFO #3 (0.6 μg/m^3).

Figure 5-15a shows the contributions of new Federal O&G emissions (Source Group X) in Colorado to annual average $PM_{2.5}$ concentrations in the three 2025 scenarios. The spatial peaks of the annual average $PM_{2.5}$ concentrations are 3.5, 0.4 and 2.9 μg/m^3 in the 2025 High, Low and Medium Development Scenarios, respectively.

Figure 5-15b displays the contributions from the WRFO (top left), CRVFO (top right), GJFO (bottom left), and RGFO #1 (bottom right) Planning Areas to annual average $PM_{2.5}$ concentrations in the 2025 High Development Scenario. The maximum contributions for these 4 Source Groups are 3.4, 0.2, 1.2, and 0.6 μg/m^3, respectively, with each of them occurring within its corresponding Planning Area.

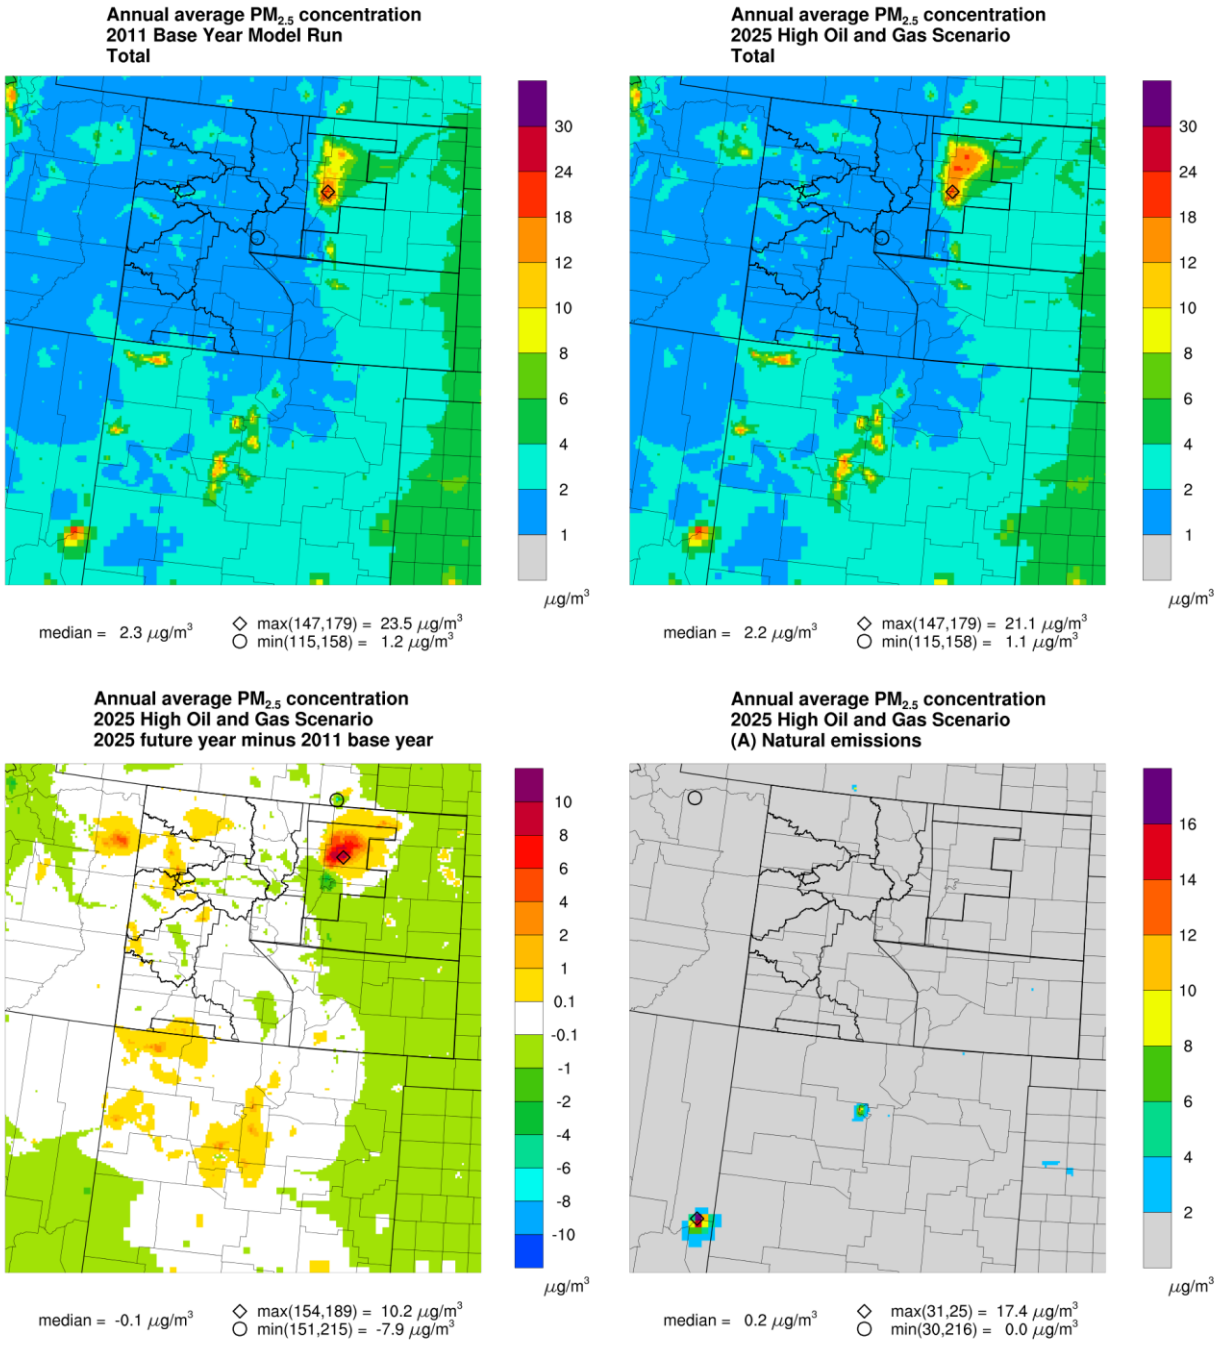

Figure 5-14a. Annual average $PM_{2.5}$ concentrations for the 2011 Base Case (top left), 2025 High Development Scenario (top right), 2025 High minus 2011 differences (bottom left) and Natural Emissions (bottom right).

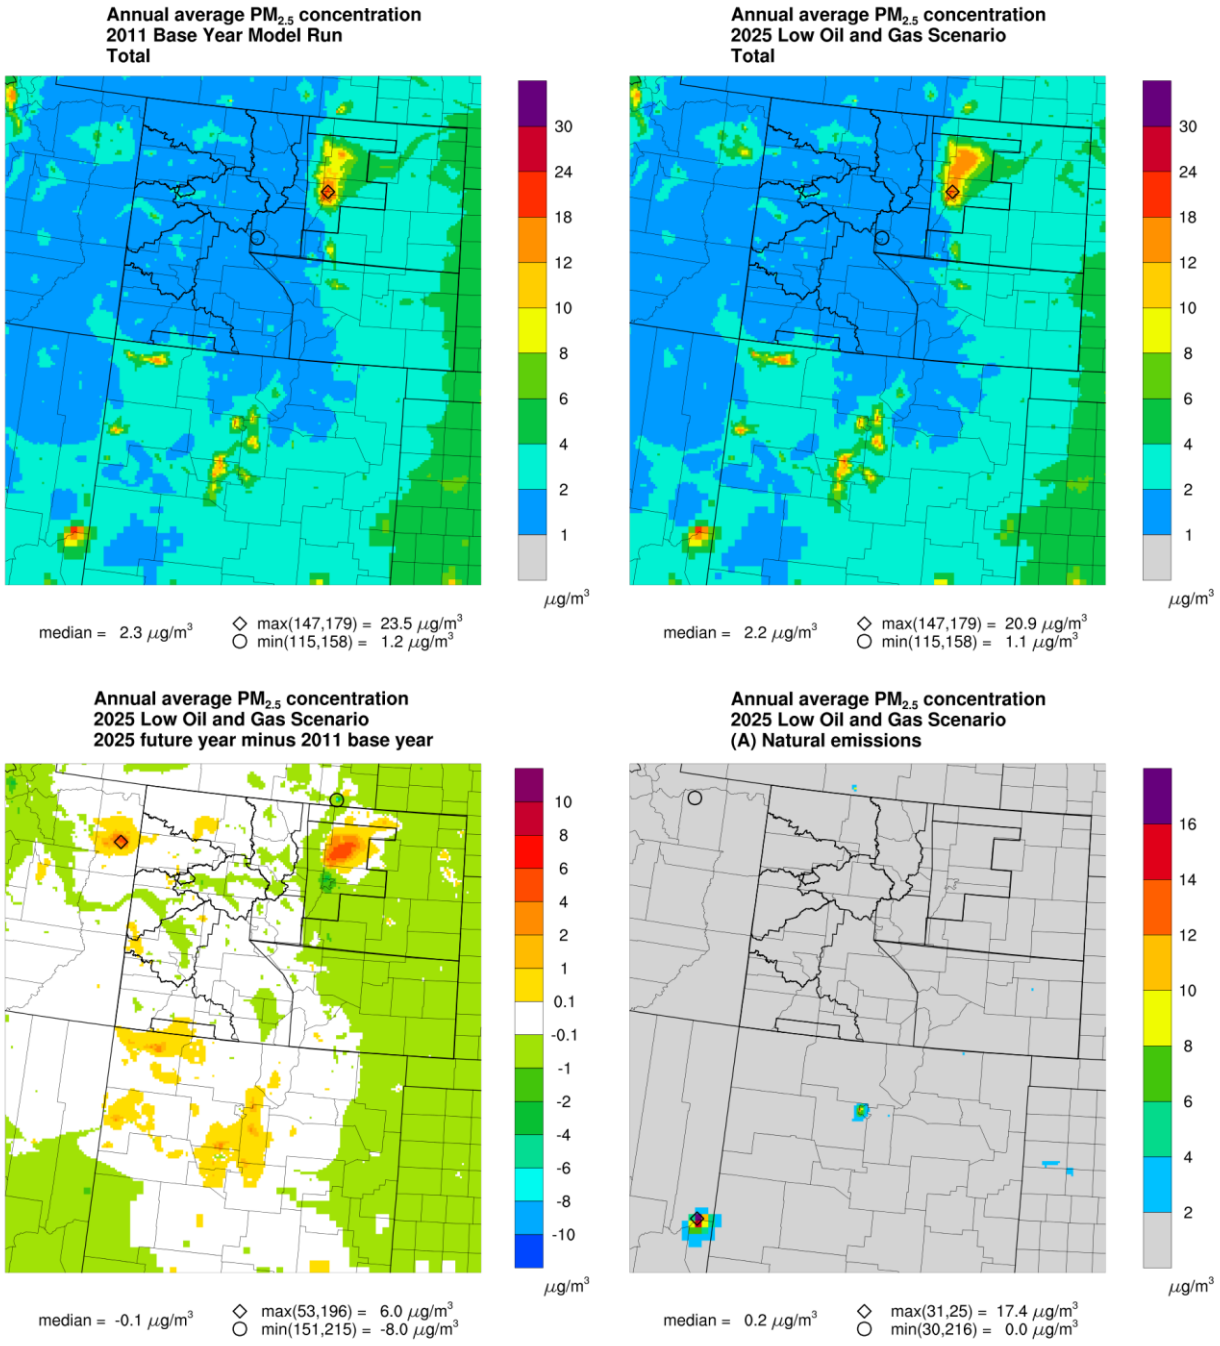

Figure 5-14b. Annual average $PM_{2.5}$ concentrations for the 2011 Base Case (top left), 2025 Low Development Scenario (top right), 2025 Low minus 2011 differences (bottom left) and Natural Emissions (bottom right).

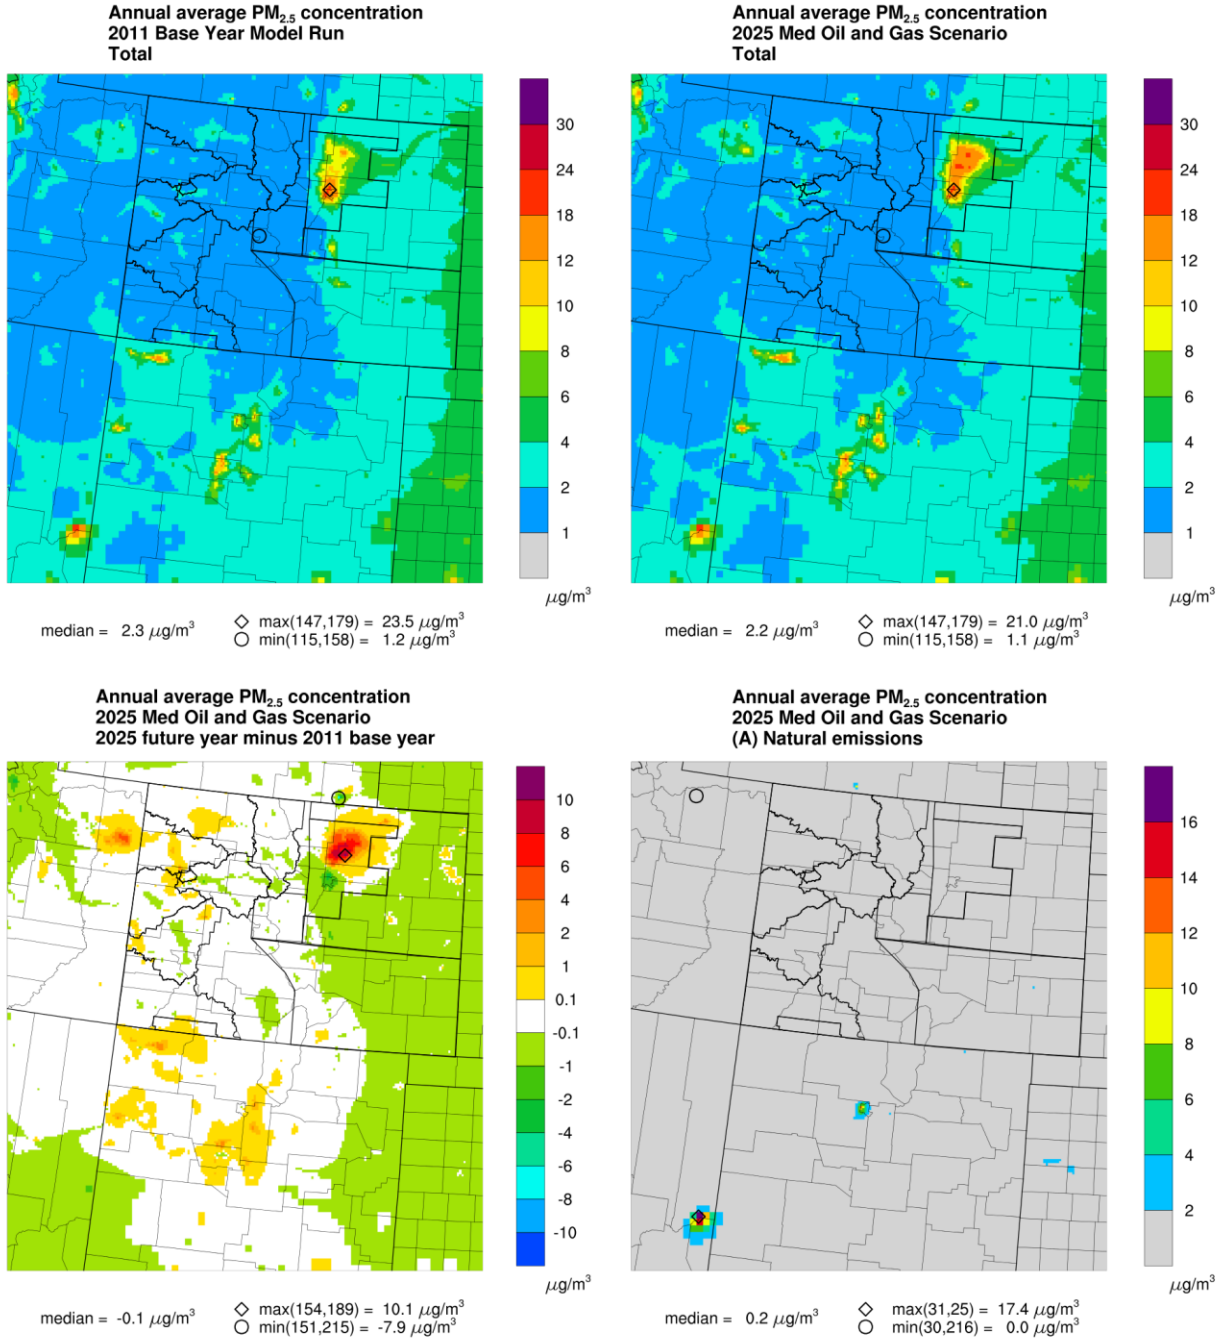

Figure 5-14c. Annual average $PM_{2.5}$ concentrations for the 2011 Base Case (top left), 2025 Medium Development Scenario (top right), 2025 Medium minus 2011 differences (bottom left) and Natural Emissions (bottom right).

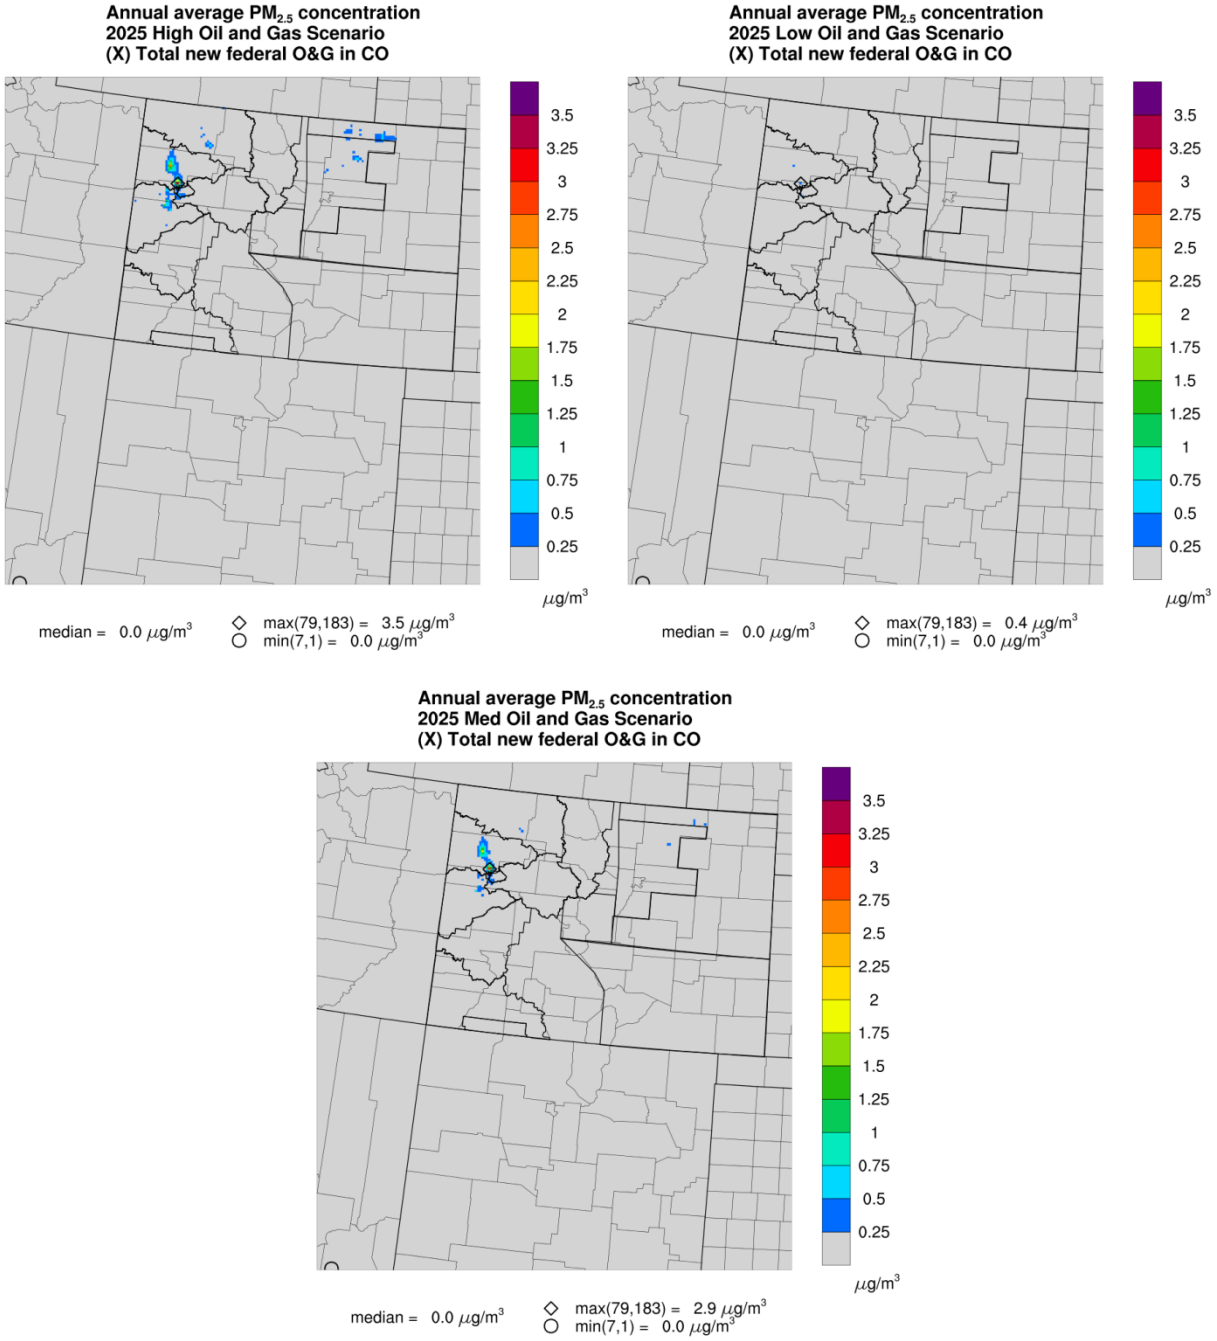

Figure 5-15a. Contribution to annual average $PM_{2.5}$ from new Federal O&G in CO (source group X) for the 2025 High (top left), Low (top right) and Medium (bottom) Development Scenarios.

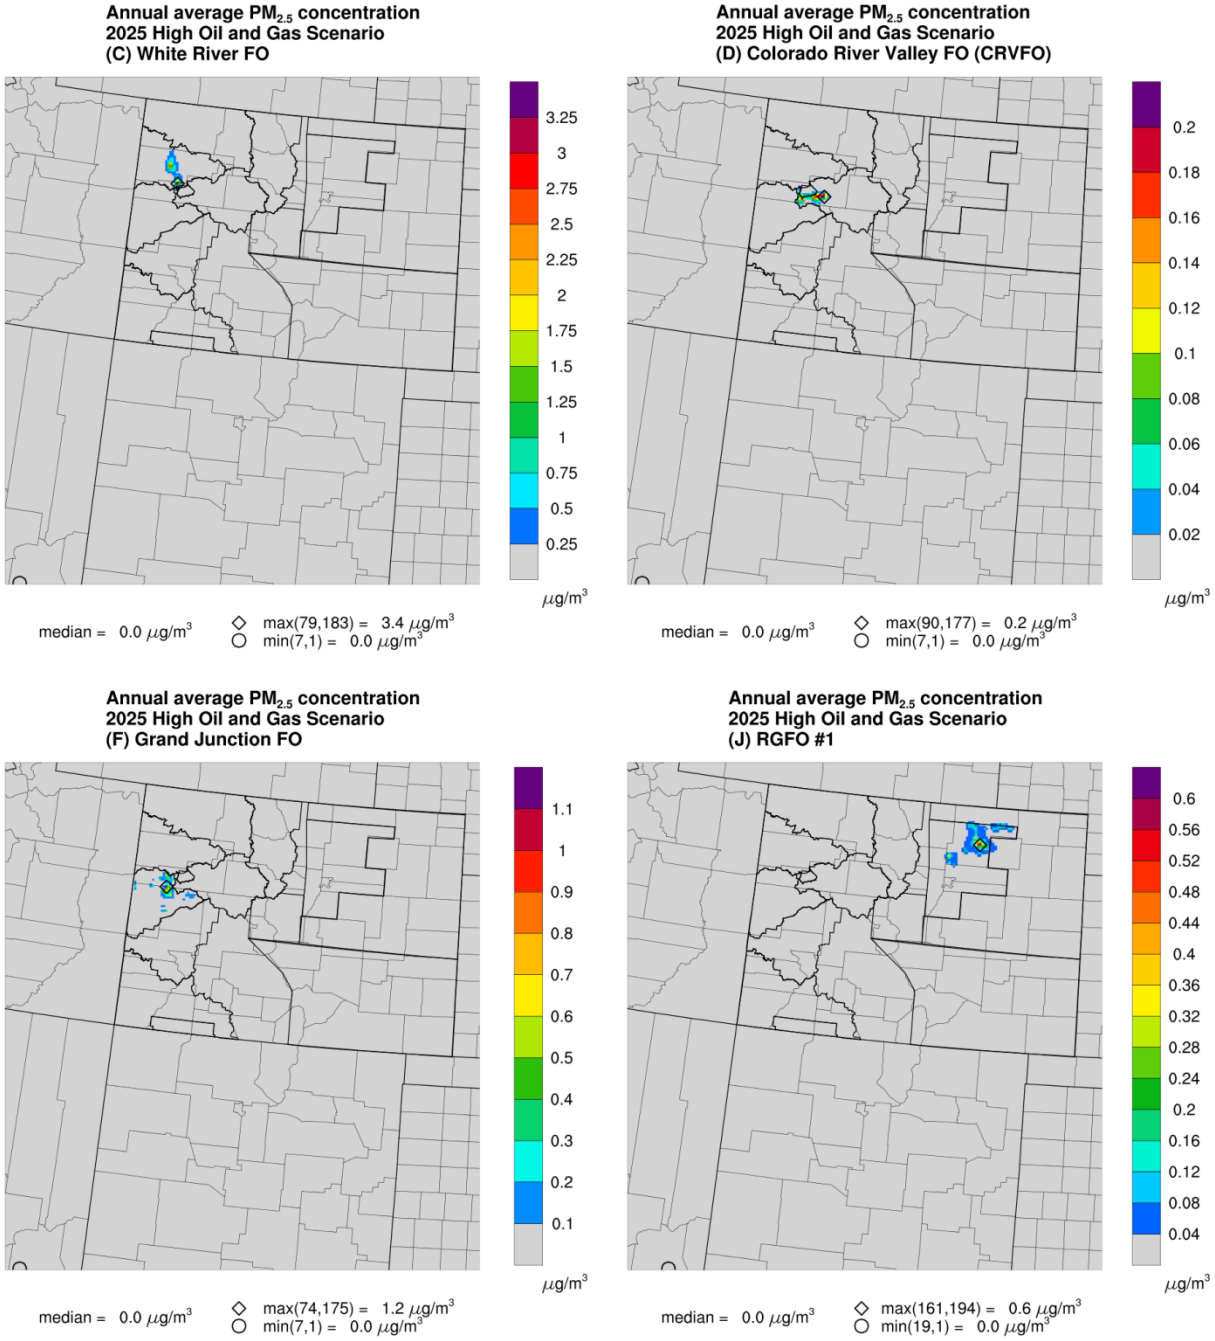

Figure 5-15b. Contribution to annual $PM_{2.5}$ concentrations due to emissions from new Federal O&G within the WRFO (top left), CRVFO (top right), GJFO (bottom left), and RGFO #1 (bottom right) Planning Areas for the 2025 High Development Scenario.

5.6.4 PM_{10} NAAQS Analysis

Figures 5-16, 5-17a and 5-17b display the 2025 High Development Scenario modeling results for 24-hour PM_{10} that can be compared to the 150 µg/m^3 24-hour PM_{10} NAAQS. Much of the discussion on 24-hour $PM_{2.5}$ also holds for 24-hour PM_{10}, although there appear to be more exceedances of the 24-hour PM_{10} NAAQS. Extremely large highest second high PM_{10} concentrations occur in the 2011 and 2025 emissions scenarios that exceed 1,000 µg/m^3 (Figure 5-16, top panels), which are largely due to natural emissions from wild fires near the AZ/NM boarder.

Figure 5-17a shows the contributions of new Federal O&G emissions CO (Source Group X) to PM_{10} concentrations in the three 2025 scenarios. The spatial peaks of the 2nd highest 24-hour PM_{10} concentrations are 19.7, 2.0 and 11.4 µg/m^3 in the 2025 High, Low and Medium Development Scenarios, respectively.

Figure 5-17b displays the contributions from the WRFO (top left), CRVFO (top right), GJFO (bottom left), and RGFO #1 (bottom right) Planning Areas to 2nd highest daily PM_{10} concentrations in the 2025 High Development Scenario. The maximum contributions for these 4 Source Groups are 19.6, 1.3, 15.4, and 9.0 µg/m^3, respectively, with each of them occurring within its corresponding Planning Area.

The contributions of all of the Source Groups and all three 2025 emission scenarios to 24-hour PM_{10} concentrations can be found in Attachment I.

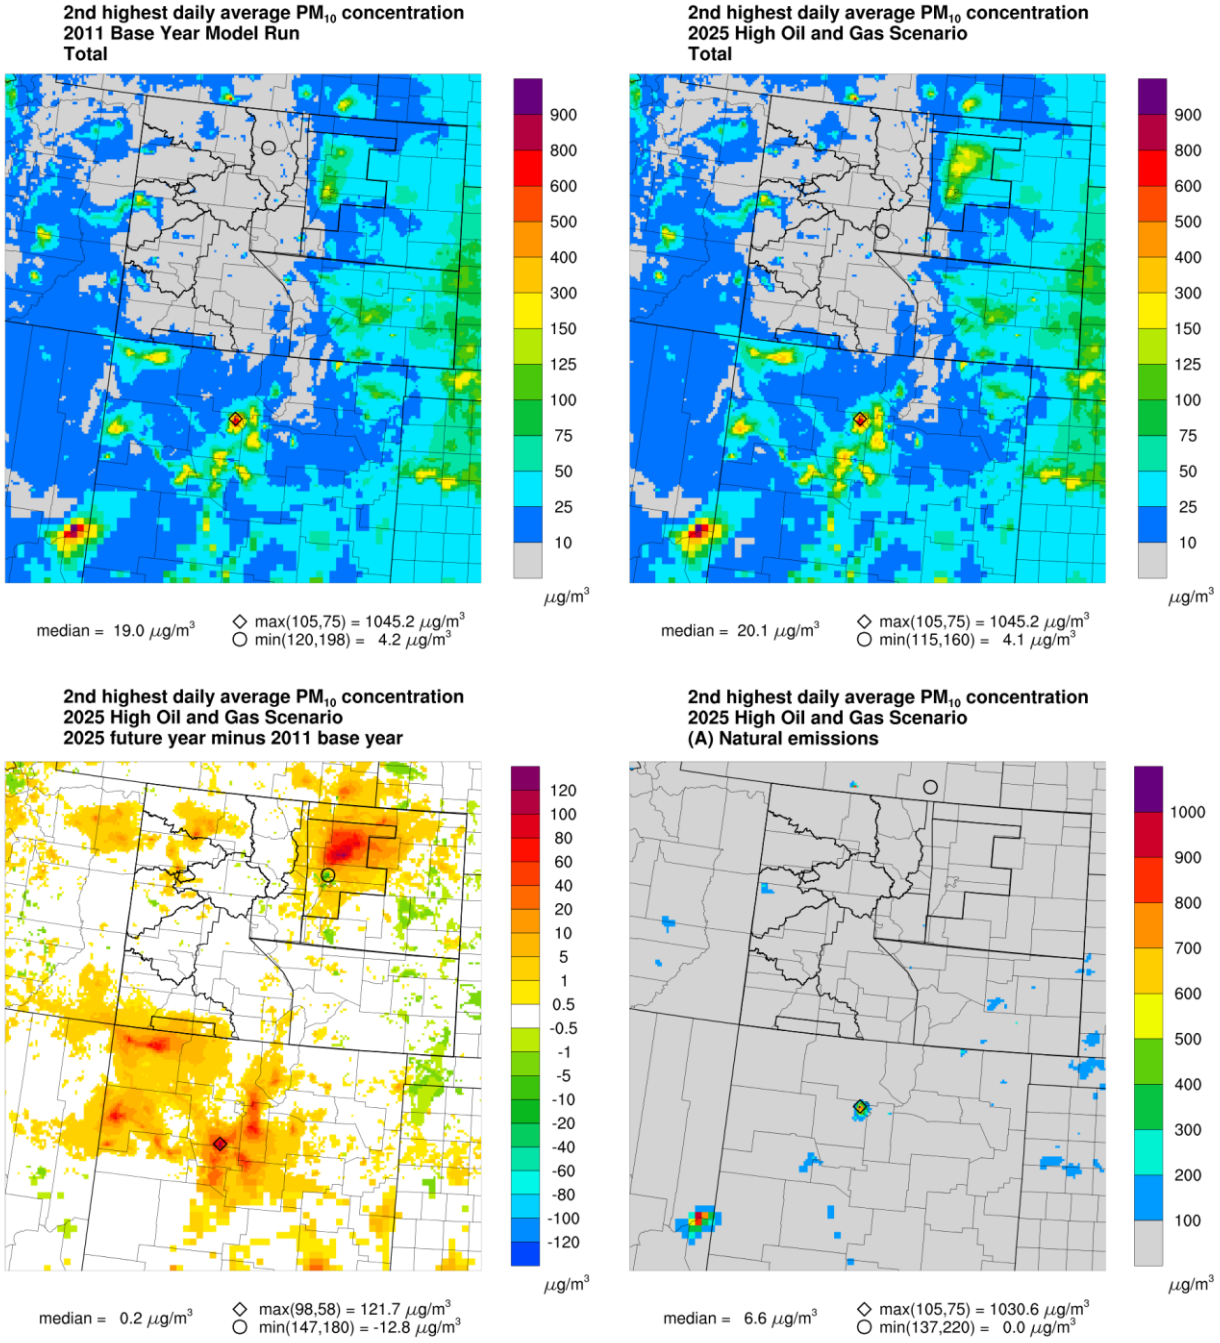

Figure 5-16. Second highest 24-hour average PM_{10} concentrations for the 2011 Base Case (top left), 2025 High Development Scenario (top right), 2025 minus 2011 differences (bottom left) and Natural Emissions (bottom right).

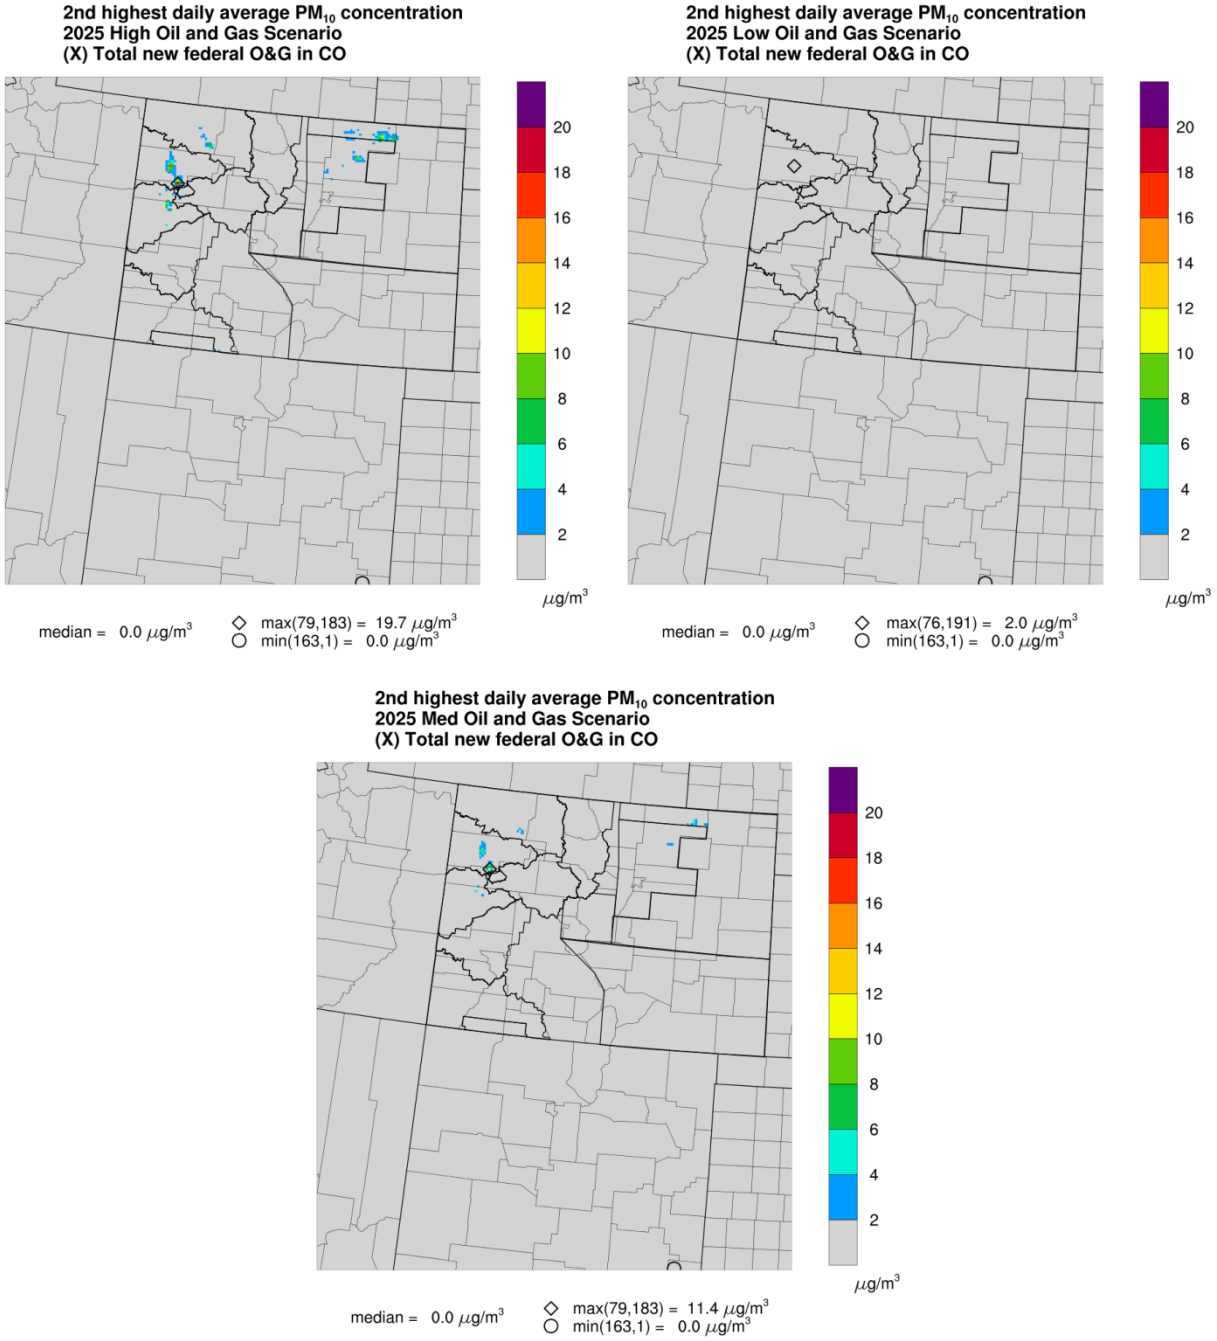

Figure 5-17a. Contribution to second highest 24-hour average PM_{10} concentrations from new Federal O&G in CO (source group X) for the 2025 High (top left), Low (top right) and Medium (bottom) Development Scenarios.

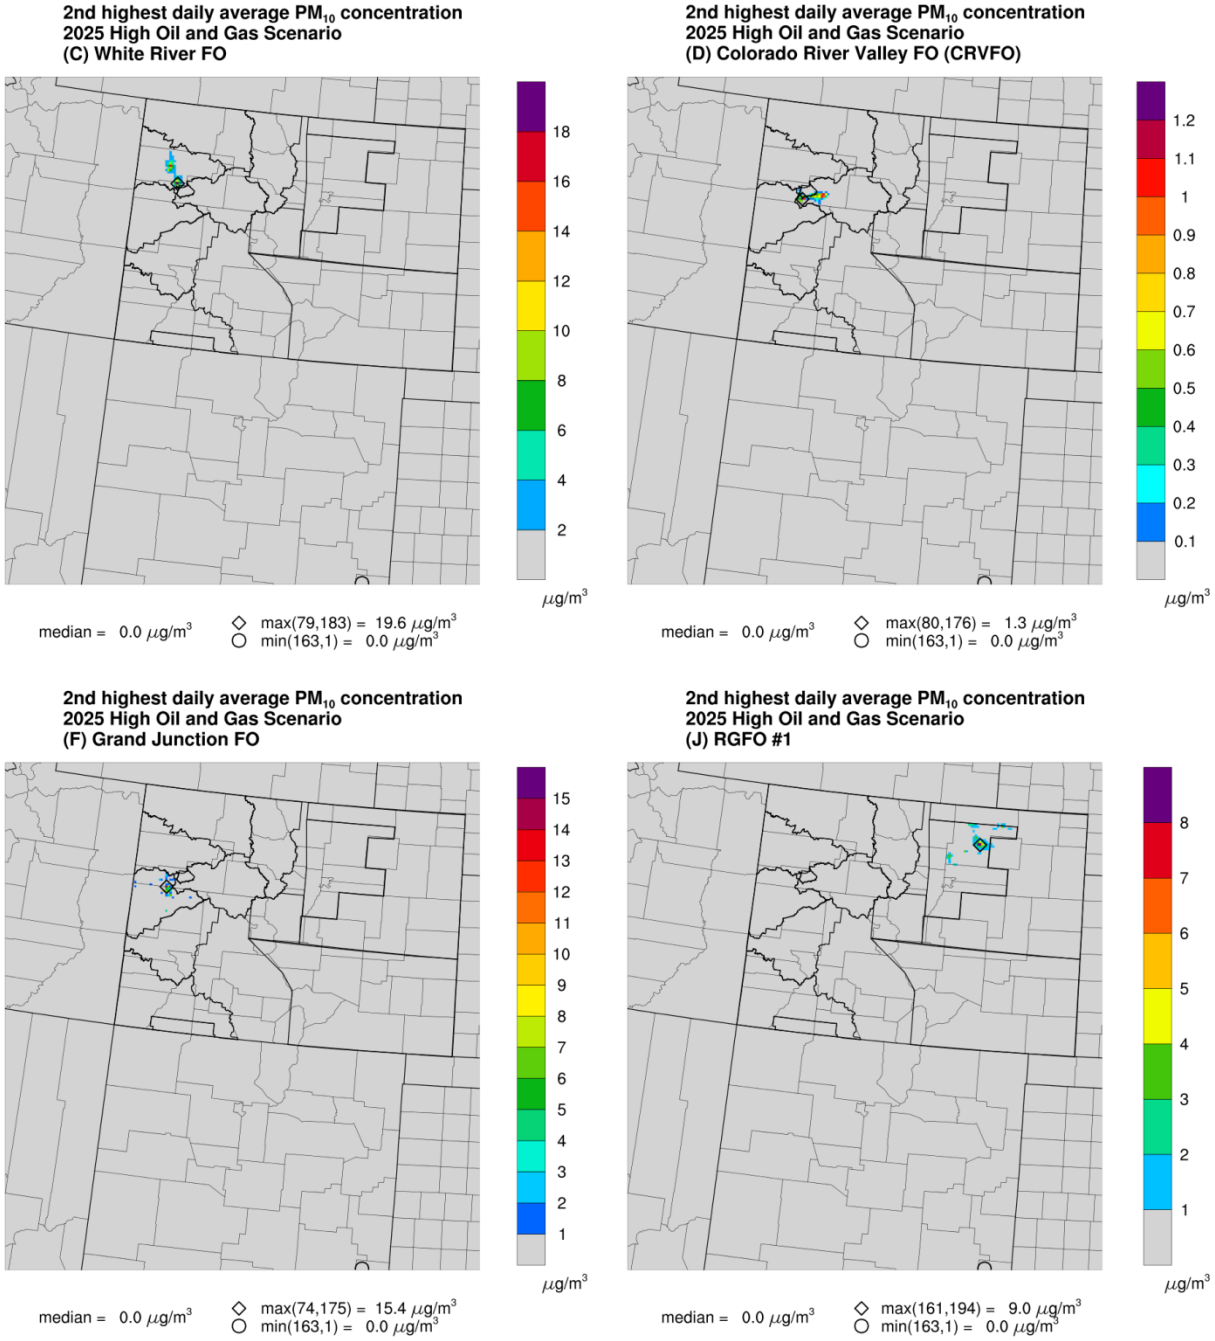

Figure 5-17b. Contribution to 2nd highest daily PM_{10} concentrations due to emissions from new Federal O&G within the WRFO (top left), CRVFO (top right), GJFO (bottom left), and RGFO #1 (bottom right) Planning Areas for the 2025 High Development Scenario.

5.6.5 SO_2 NAAQS Analysis

The 2011 Base Case and 2025 High Development Scenario, their differences and contributions of Natural Emissions to 1-hour, 3-hour and annual SO_2 concentrations are shown in Figures 5-18 through 5-21, respectively. The 1-hour SO_2 NAAQS is 75 ppb and it is exceeded when the colors in Figure 5-18 are yellow or hotter. Natural emissions from wild fires are the primary cause for the two exceeding areas in Arizona and New Mexico. 1-hour SO_2 is overall below 30 ppb in most places and shows reduction from the 2011 base year to the 2025 High Development Scenario. Similarly, as shown in Figures 5-19 through 5-22, 3-hour, 24-hour and annual average SO_2 are all well below the corresponding NAAQS/CAAQS/NMAAQS, with the exception of small areas affected by extreme wild fires, and all of them show a reduction from the 2011 base year to the 2025 High Development Scenario.

As an example, Figure 5-22 shows contribution to fourth highest daily maximum hourly SO_2 concentrations due to emissions from new Federal O&G and mining in CO (Source Group A2) (left) and new Federal O&G and mining and non-Federal O&G in CO (Source Group A3) (right). The contributions from both A2 and A3 Source Groups are relatively small with a maximum of 2.8 ppb in the White River FO. Spatial maps showing the SO_2 contributions from all other Source Groups and 2025 emission scenarios are given in Attachment I.

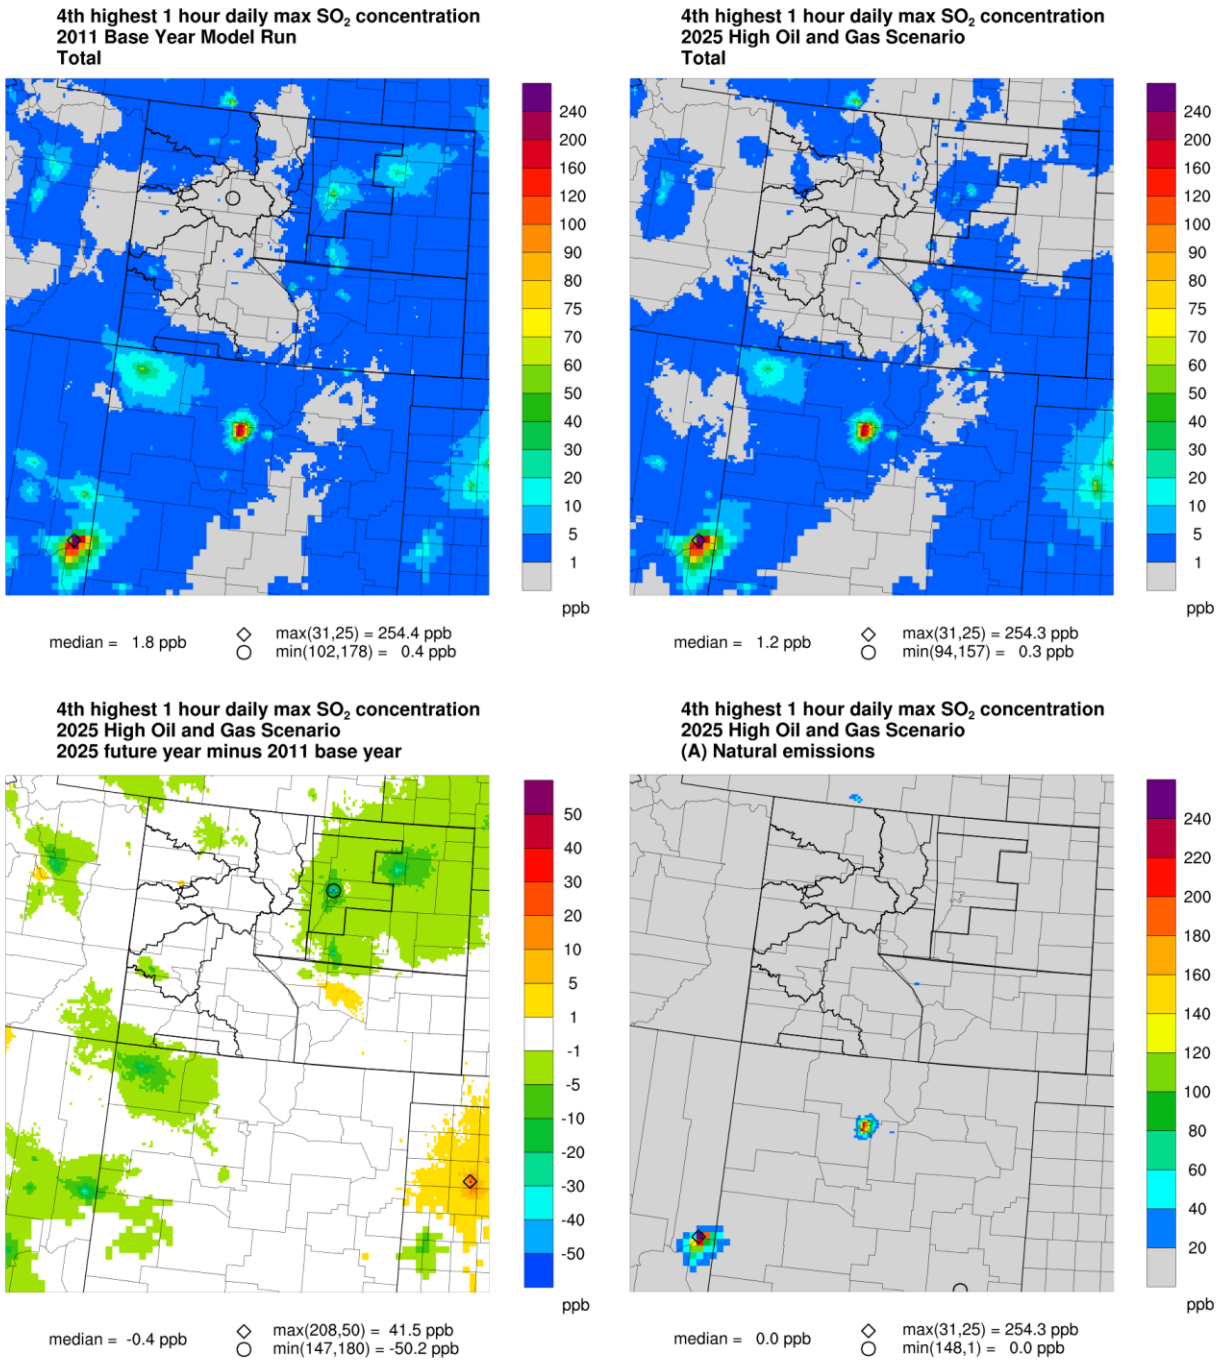

Figure 5-18. Fourth highest (99th percentile) daily maximum 1-hour average SO_2 concentrations for the 2011 Base Case (top left), 2025 High Development Scenario (top right), 2025 minus 2011 differences (bottom left) and Natural Emissions (bottom right).

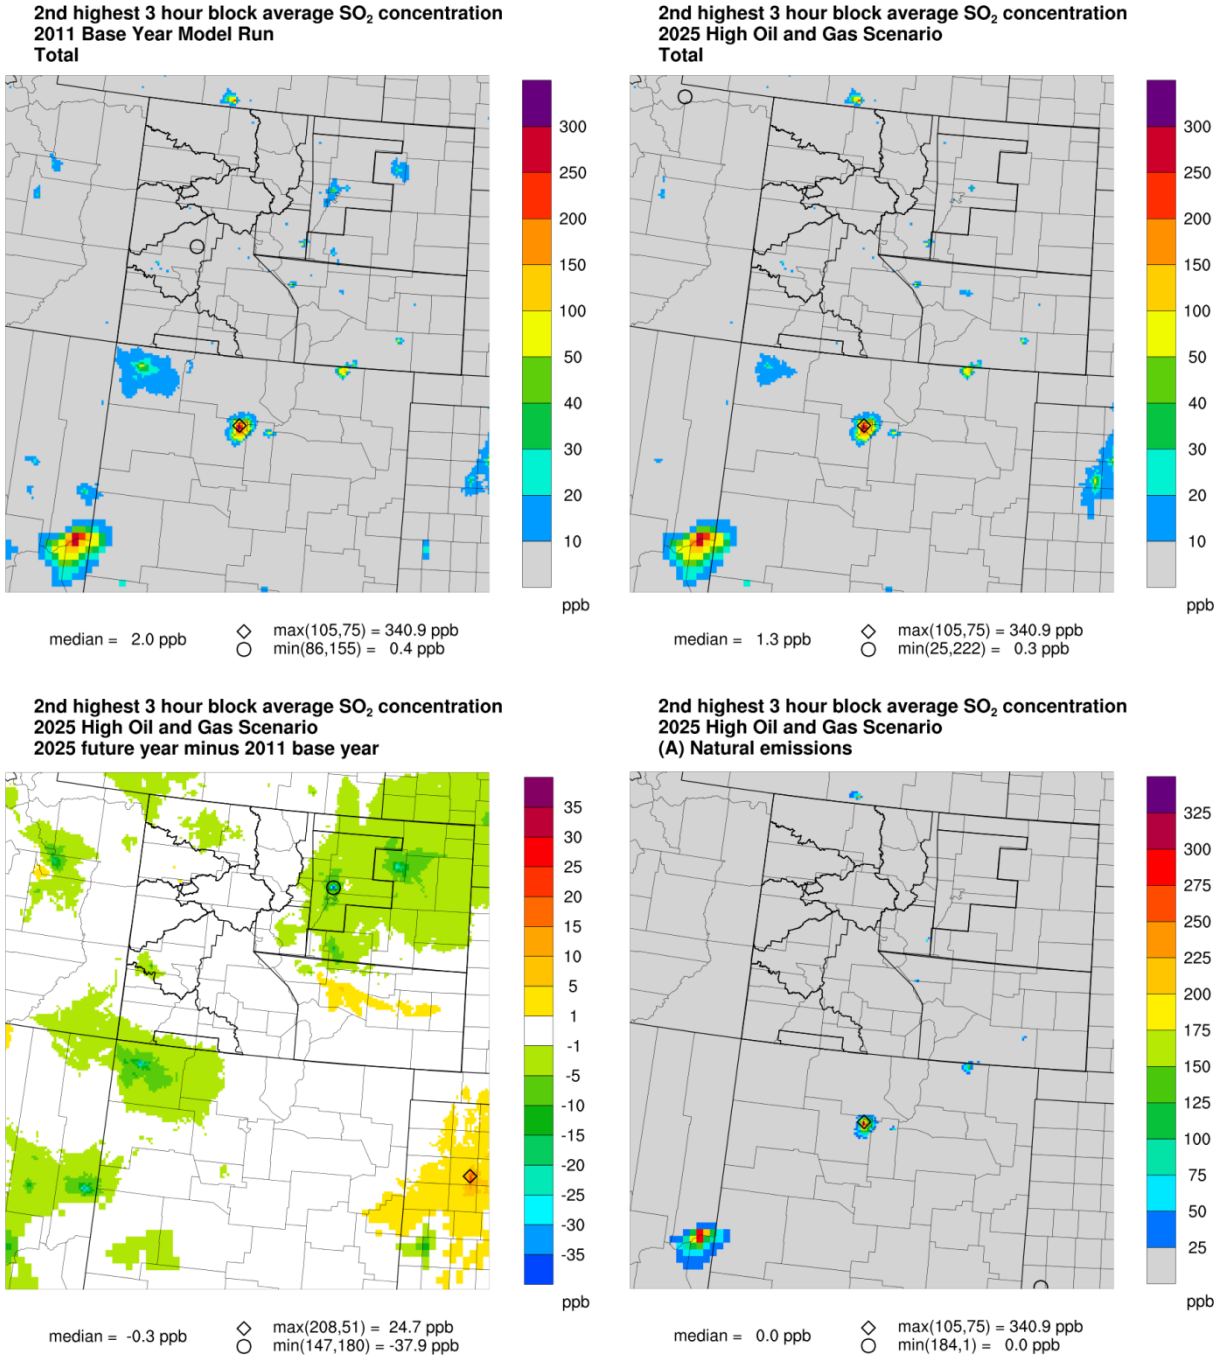

Figure 5-19. Second highest 3-hour average SO_2 concentrations for the 2011 Base Case (top left), 2025 High Development Scenario (top right), 2025 minus 2011 differences (bottom left) and Natural Emissions (bottom right).

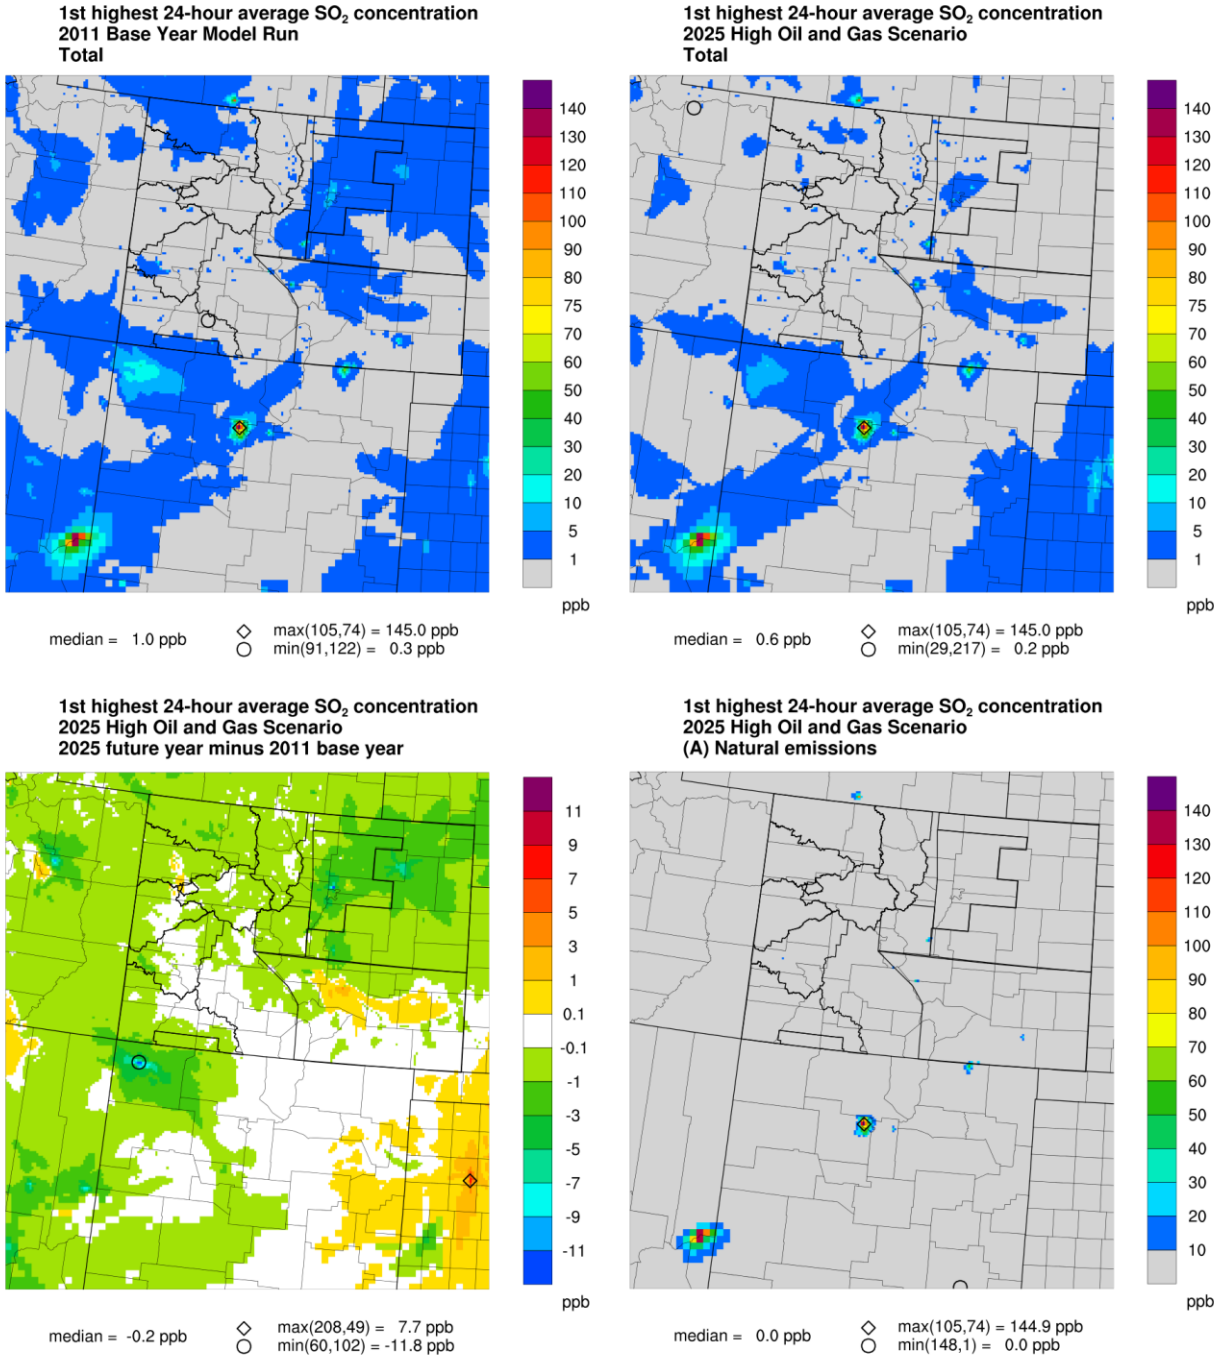

Figure 5-20. 24-hour average SO_2 concentrations for the 2011 Base Case (top left), 2025 High Development Scenario (top right), 2025 minus 2011 differences (bottom left) and Natural Emissions (bottom right).

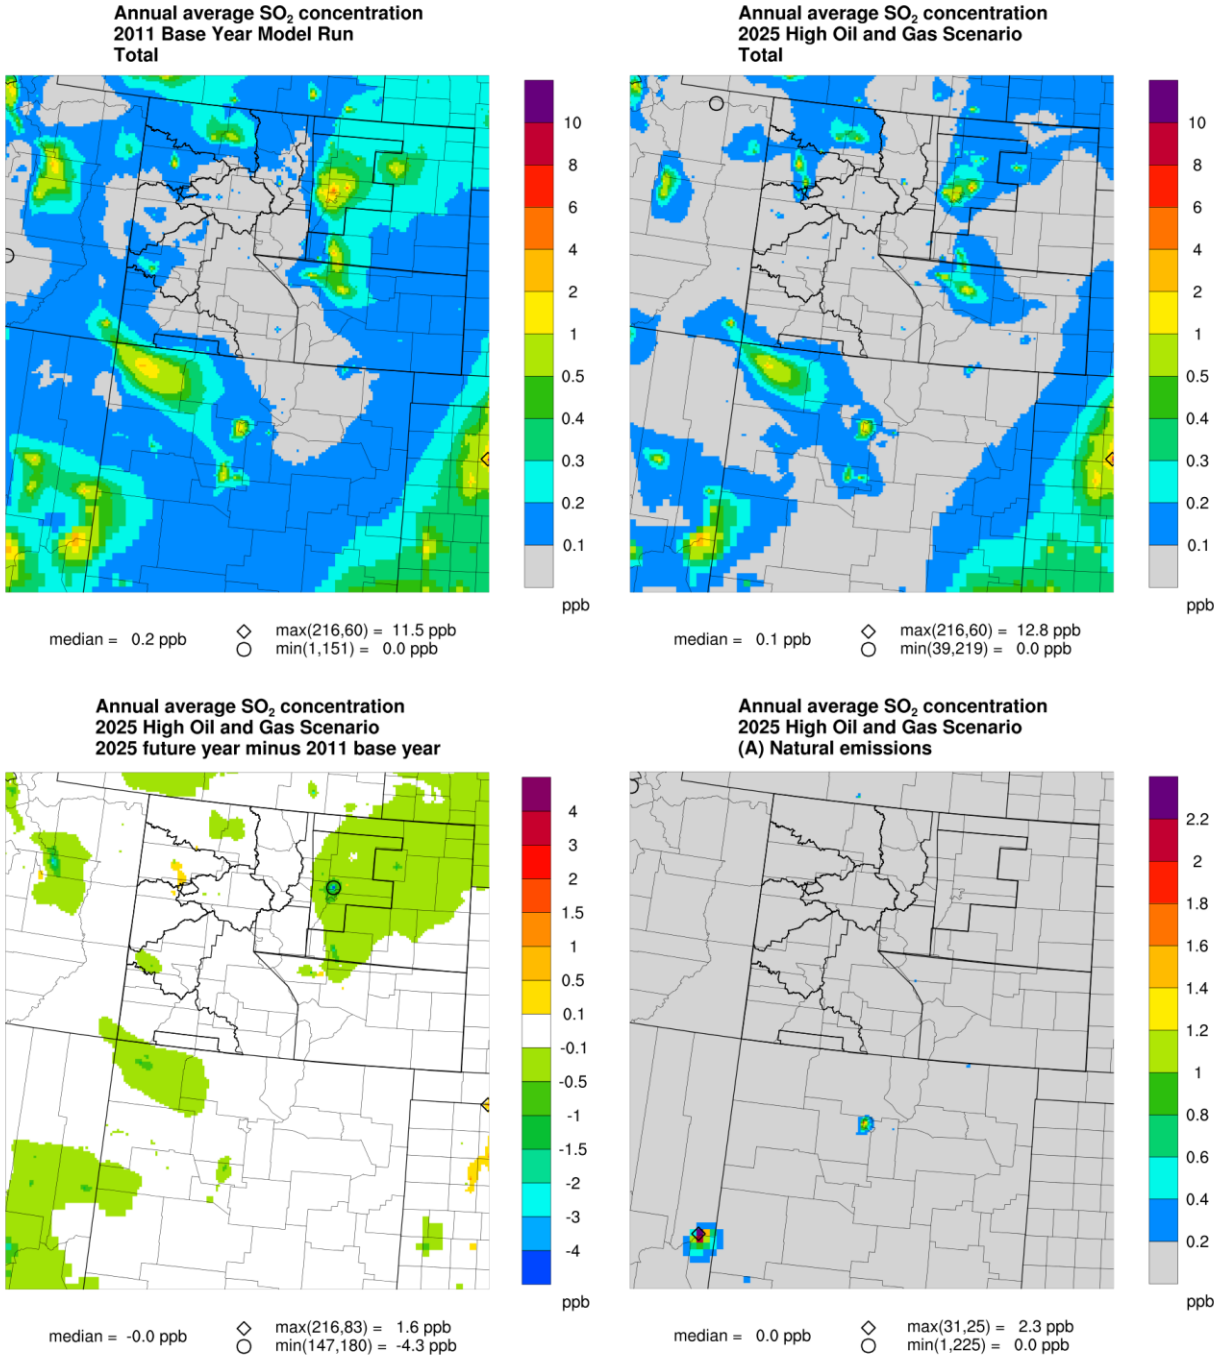

Figure 5-21. Annual average SO_2 concentrations for the 2011 Base Case (top left), 2025 High Development Scenario (top right), 2025 minus 2011 differences (bottom left) and Natural Emissions (bottom right).

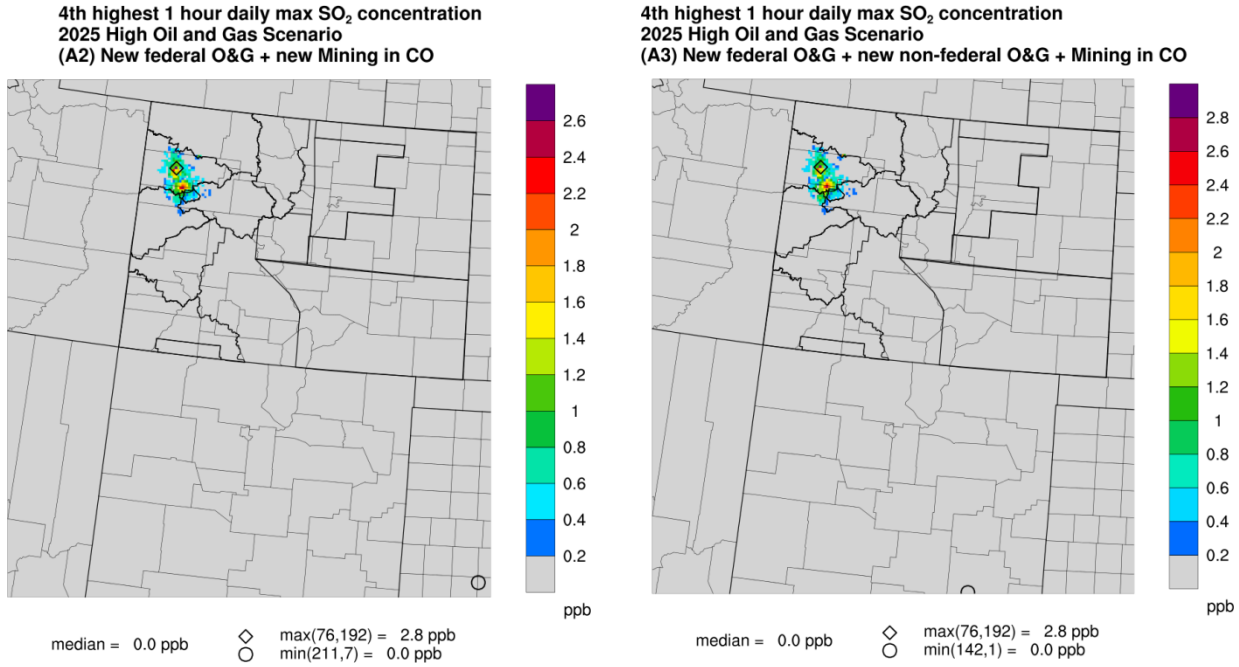

Figure 5-22. Contribution to fourth highest daily maximum hourly SO_2 concentrations due to emissions from new Federal O&G and mining in CO (Source Group A2) (left) and new Federal O&G and mining and non-Federal O&G in CO (Source Group A3) (right).

5.6.6 NO_2 NAAQS Analysis

Figure 5-23a displays spatial maps of the 98th percentile daily maximum 1-hour NO_2 concentrations for the 2011 Base Case and 2025 High, Low and Medium Development Scenarios with the differences in NO_2 concentrations between the 2025 emissions scenarios and the 2011 Base Case shown in Figure 5-23b. The 1-hour NO_2 NAAQS is 188 µg/m^3 (100 ppb) and the tile plots in Figure 5-23a have a cut-point at 100 ppb. In all four scenarios, the highest 1-hour NO_2 concentration occurs near the AZ/NM border that is above the NAAQS. This NO_2 exceedance is due to wildfires and is present in the 2011 Base Case and 2025 scenarios since wildfires were assumed to be unchanged.

The differences in 1-hour NO_2 concentrations between the 2011 and 2025 emission scenarios (Figure 5-23b) indicate increases in RGFO #1, WRFO, GJFO, and Uncompahgre FO, large increases in northern, as well as eastern Arizona and New Mexico. The largest increases are 64.1, 54.2, and 64.0 ppb for the High, Low, Medium Scenarios, respectively, all of which are on the southern border of Uncompahgre FO.

Figure 5-23d-f show the contributions from new Federal O&G in CO (source group X), new Federal O&G and mining in CO (source group A2), new Federal O&G, new non-Federal O&G and mining in CO (source group A3), and all EGUs in CO and NM (source group A4) to the 98th percentile daily maximum 1-hour NO_2 concentrations for each of the High, Low and Medium Development Scenarios, respectively. Source Group X has maximum contributions for the High, Medium and Low Development Scenarios of 64.2, 11.3 and 61.3 ppb, respectively, all of which occur near the southern border of WRFO. The maximum contributions from Source Group A2 are 64.2, 40.3, and 61.3 ppb for the three scenarios, while the maximum contributions from Source Group A3 are 65.4, 40.3, and 61.3 ppb for the three scenarios. The maximum contributions from all EGUs in CO and NA are 18.3 ppb for all three scenarios, while the slightly different value of 18.4 ppb for the Low Development Scenario is due to different chemistry among different emission scenarios.

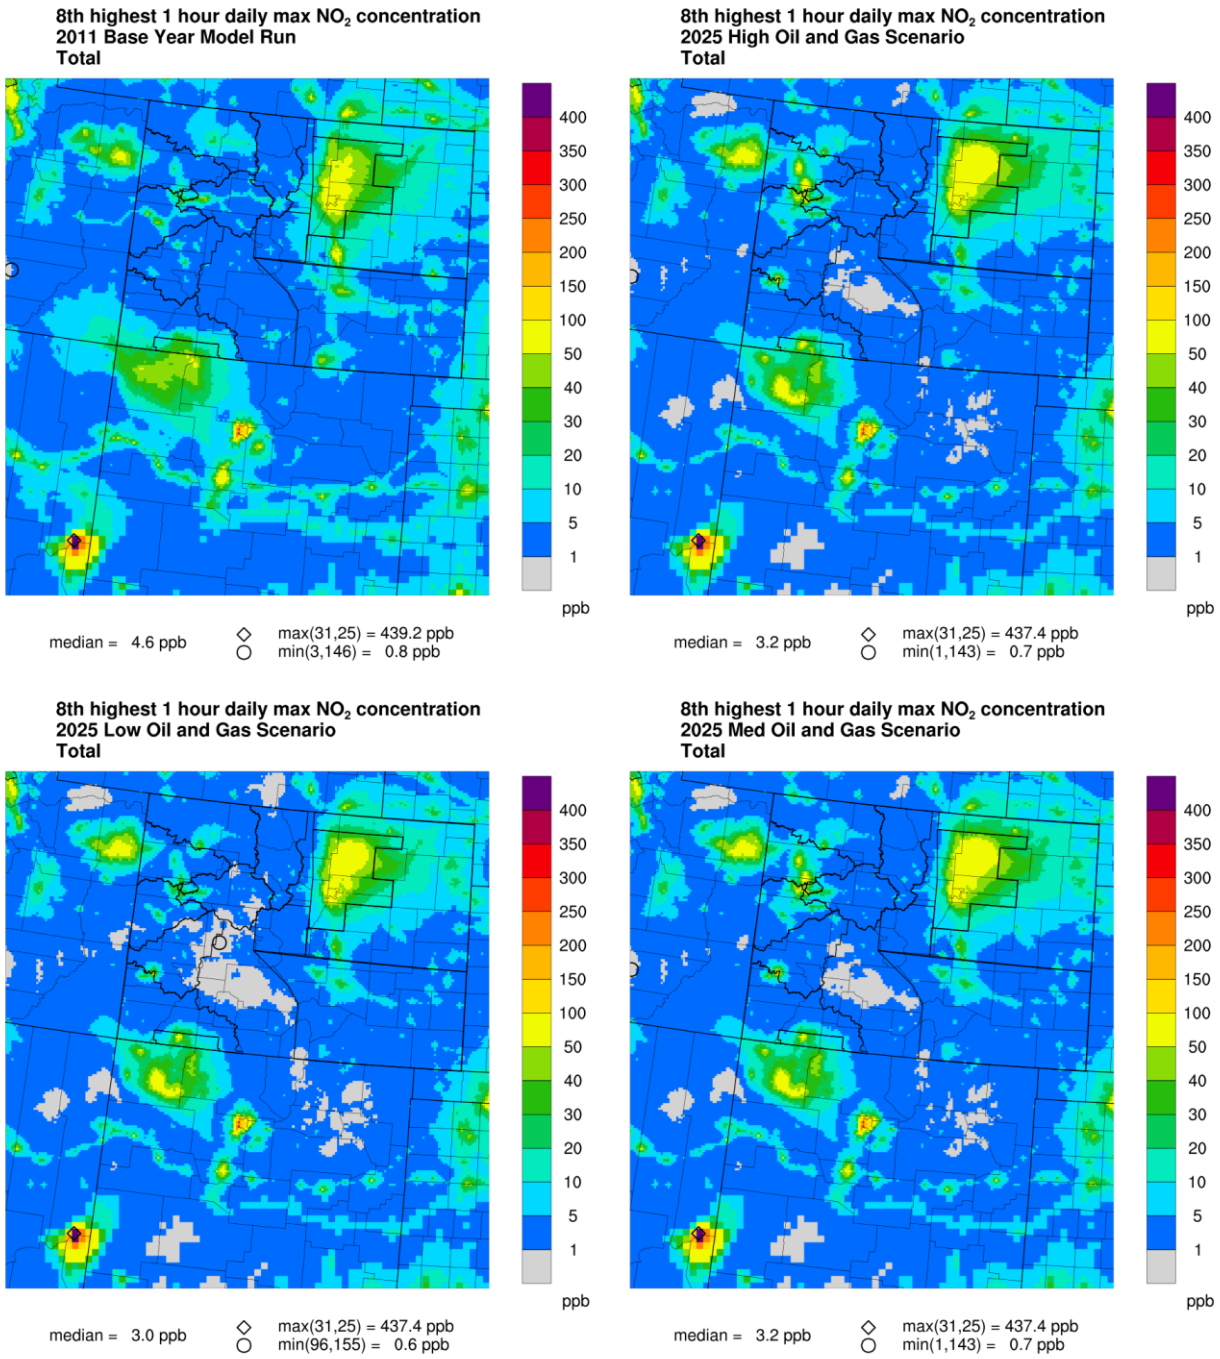

Figure 5-23a. Eighth highest (98th percentile) daily maximum 1-hour average NO_2 concentrations for the 2011 Base Case (top left), 2025 High Development Scenario (top right), 2025 Low Development Scenario (bottom left) and 2025 Medium Development Scenario (bottom right).

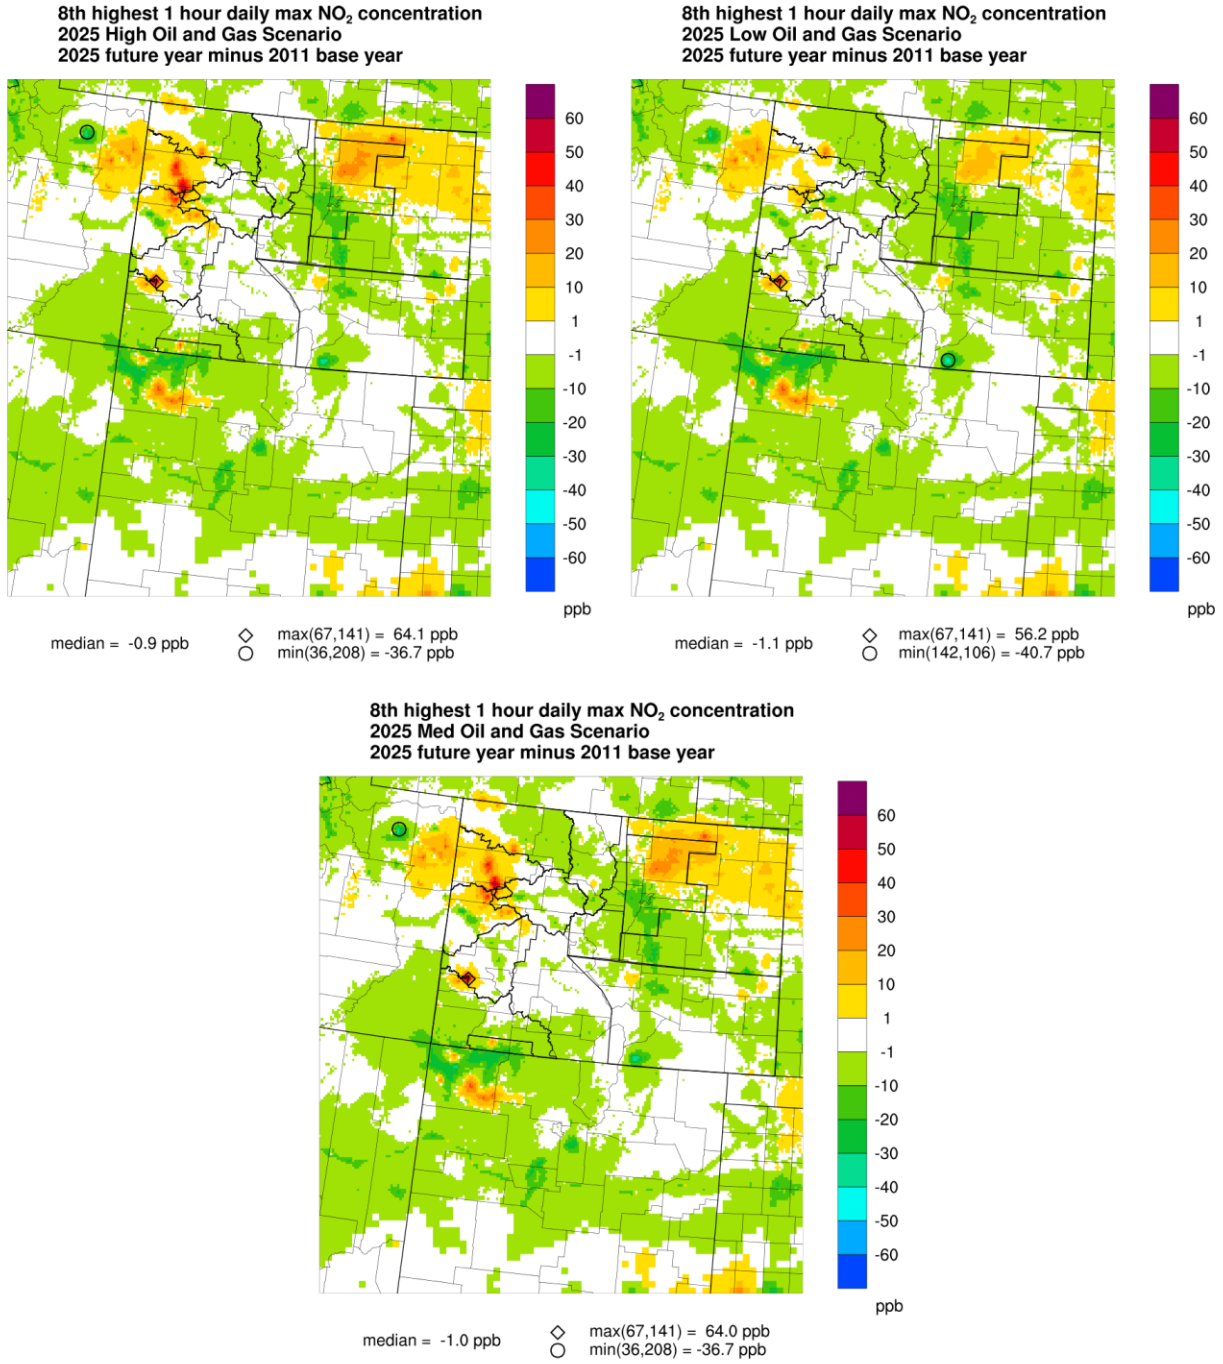

Figure 5-23b. Differences in eighth highest (98th percentile) daily maximum 1-hour average NO_2 concentrations between the 2025 emission scenarios and the 2011 Base Case for the 2025 High (top left), Low (top right) and Medium (bottom) Development Scenarios.

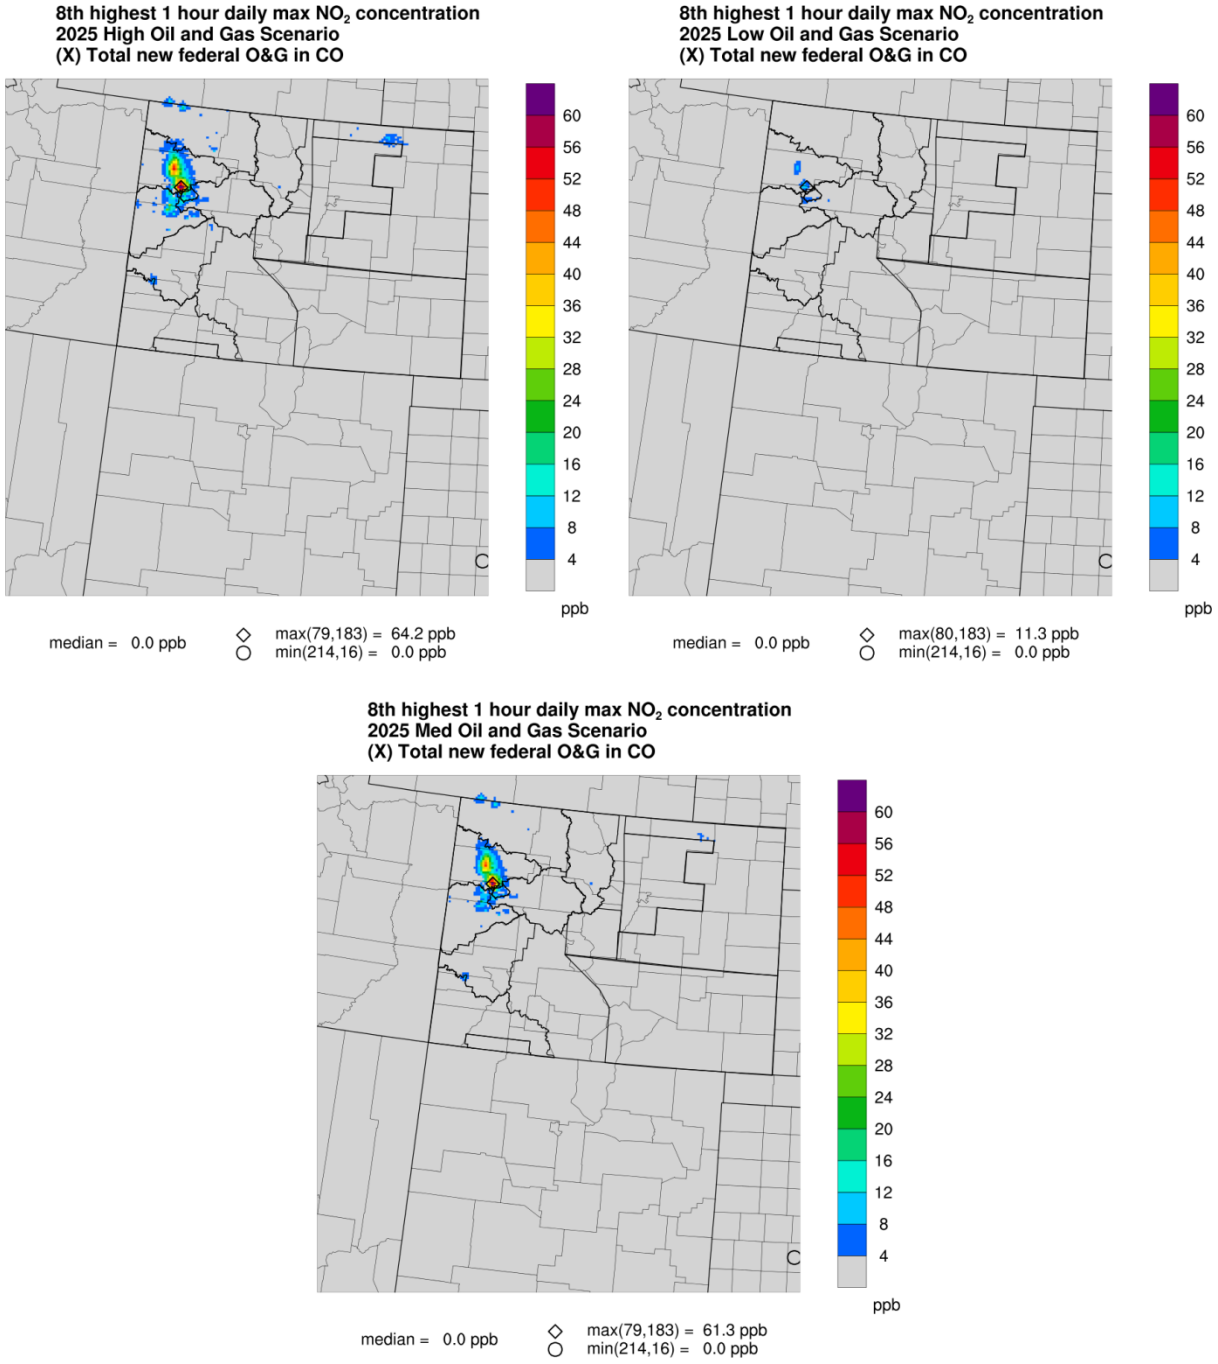

Figure 5-23c. Contributions from new Federal O&G in CO (source group X) to the eighth highest (98th percentile) daily maximum 1-hour average NO_2 concentrations in the 2025 High (top left), Low (top right) and Medium (bottom) Development Scenarios.

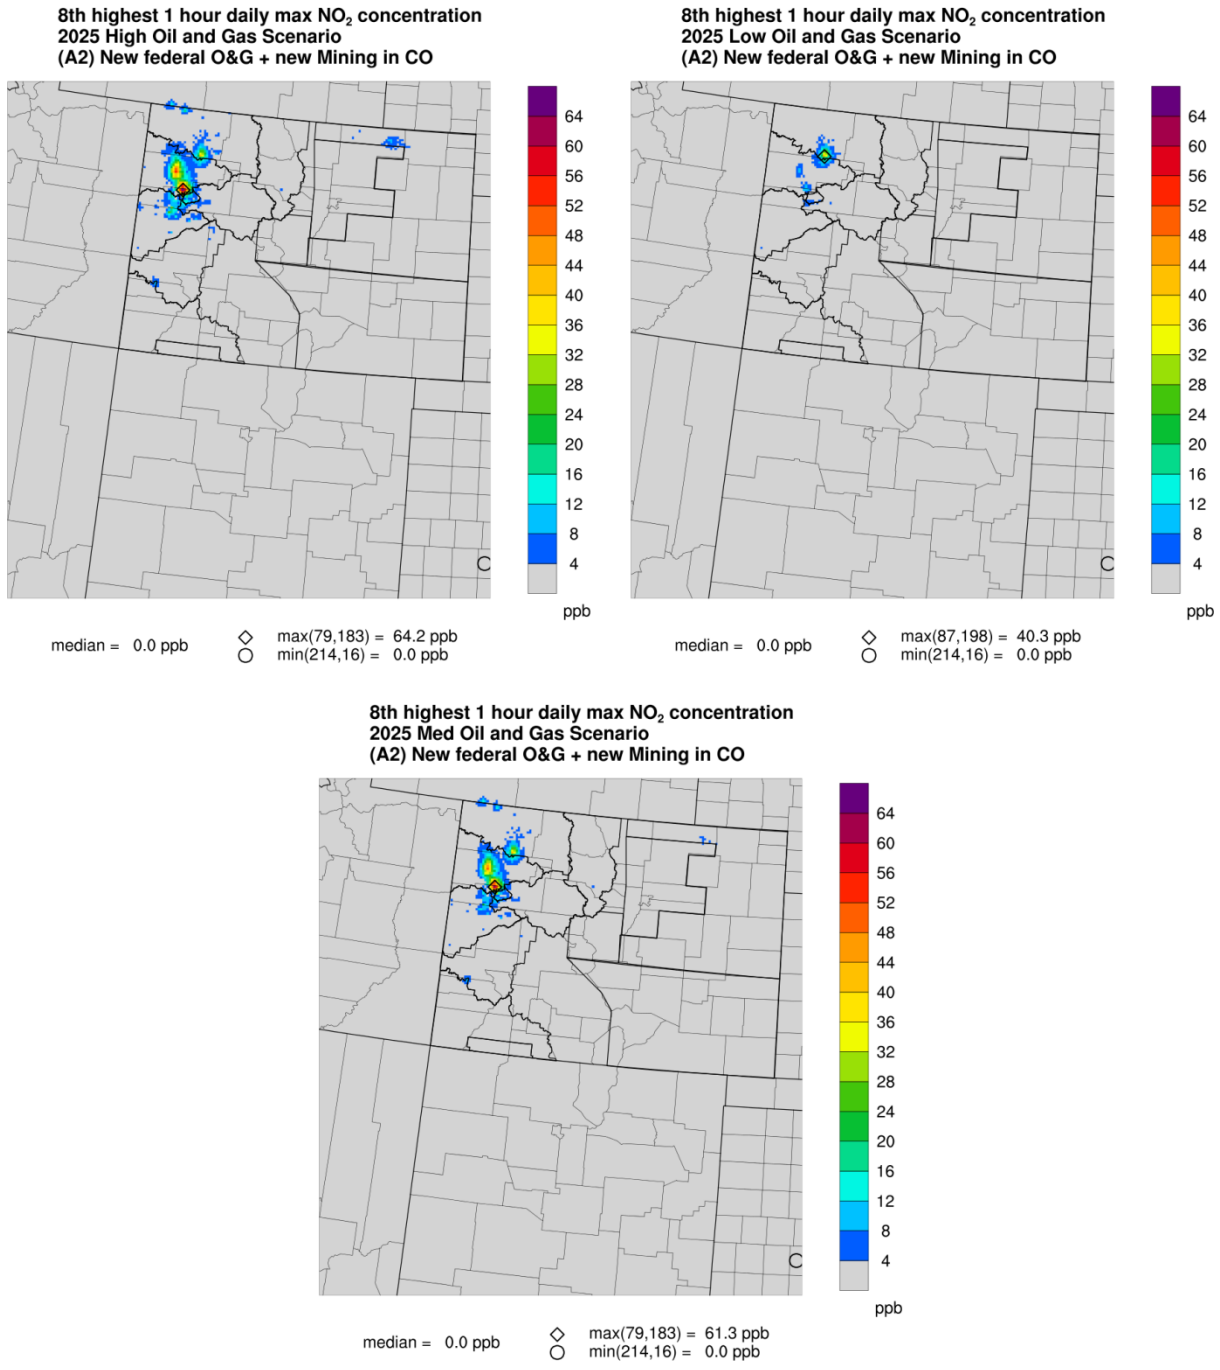

Figure 5-23d. Contributions from new Federal O&G and mining in CO (source group A2) to the eighth highest (98th percentile) daily maximum 1-hour average NO_2 concentrations in the 2025 High (top left), Low (top right) and Medium (bottom) Development Scenarios.

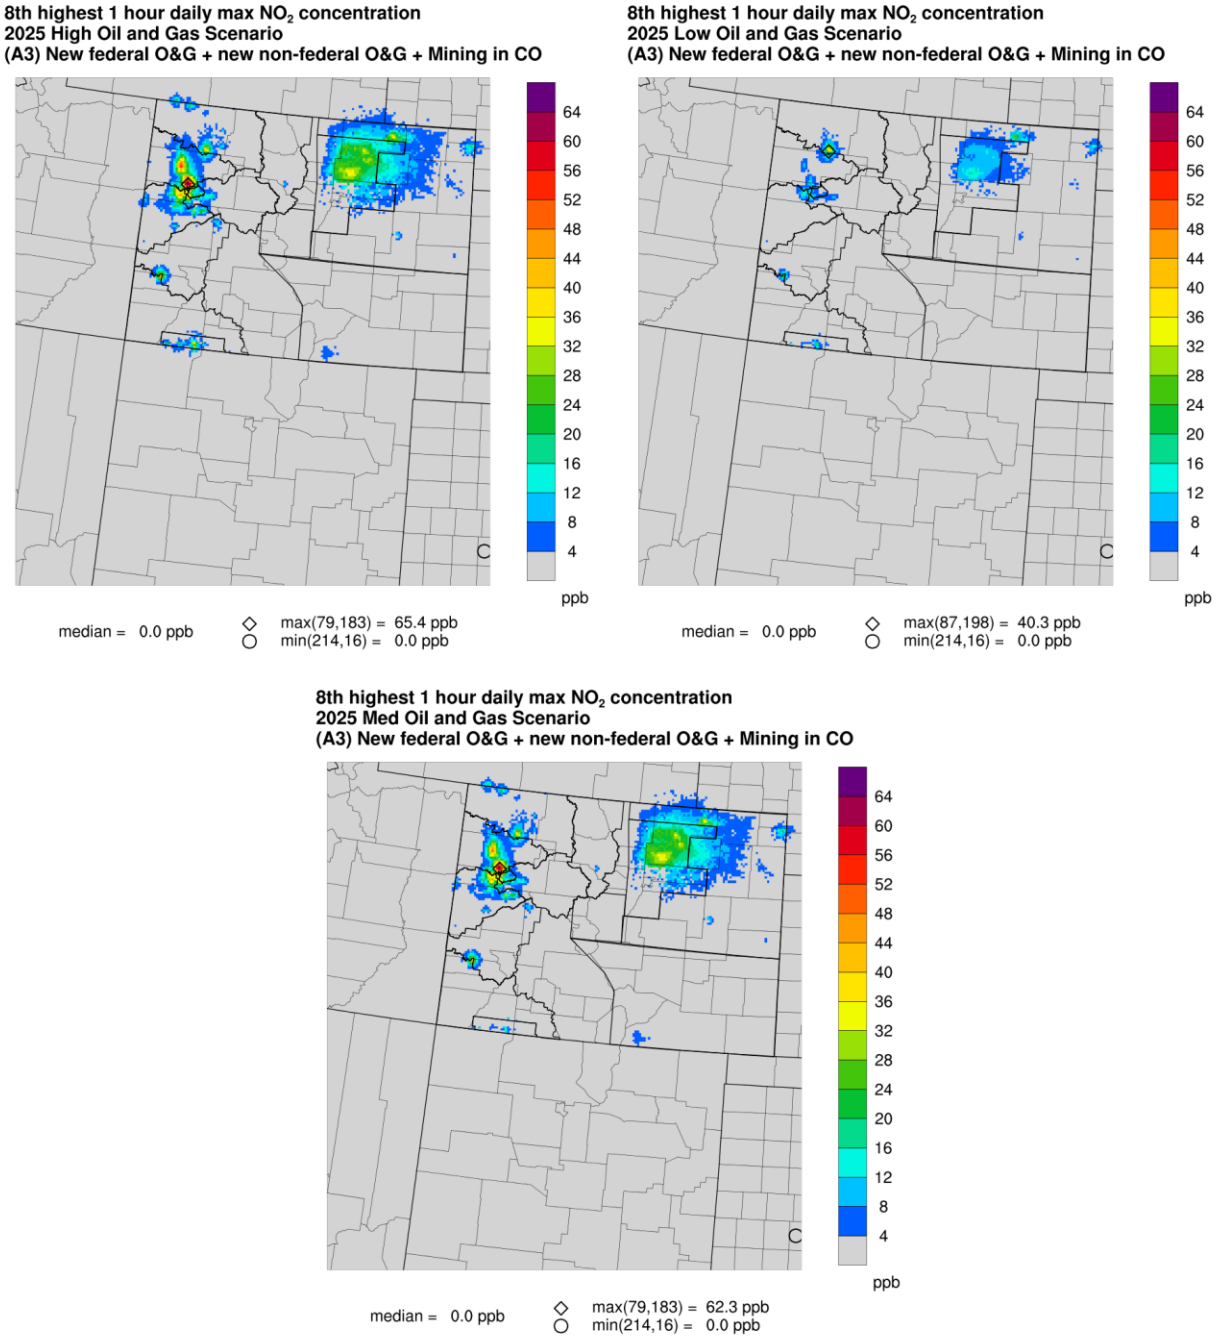

Figure 5-23e. Contributions from new Federal O&G, new non-Federal O&G and mining in CO (source group A3) to the eighth highest (98th percentile) daily maximum 1-hour average NO_2 concentrations in the 2025 High (top left), Low (top right) and Medium (bottom) Development Scenarios.

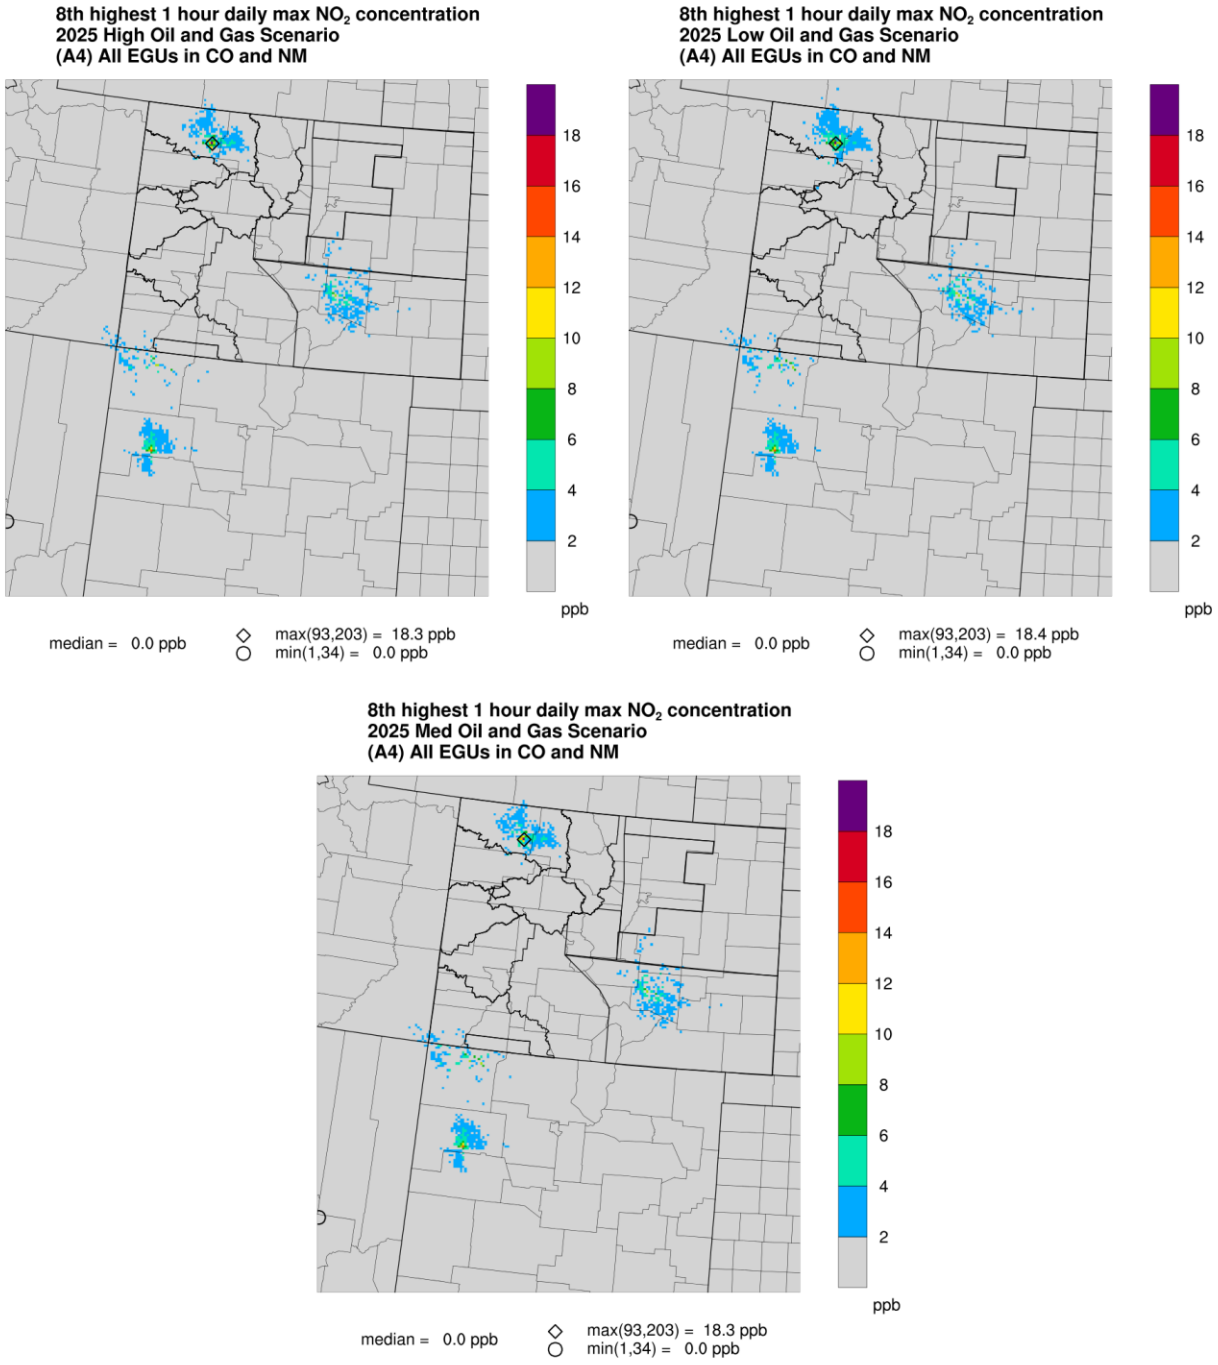

Figure 5-23f.Contributions from all EGUs in CO and NM (source group A4) to the eighth highest (98th percentile) daily maximum 1-hour average NO_2 concentrations in the 2025 High (top left), Low (top right) and Medium (bottom) Development Scenarios.

5.7 W126 Cumulative Ozone Exposure Index

Figure 5-24 shows spatial maps of W126 Cumulative Ozone Exposure Index for 2011 Base Year (upper left), 2025 High Development Scenario (upper right), and their difference (lower left). The annual W126 index ranges from 4 to 35 ppm-hours for the 2011 Base Year, and ranges from 7 to 32 ppm-hours for the 2025 High Scenario. The maximum W126 is seen in New Mexico for both the 2011 Base Year and the 2025 High Scenario. Reduction of W126 from 2011 to 2025 is seen over most areas within the 12/4 km domain except at some locations near Denver and in northwestern New Mexico. Annual W126 index for the 2025 Low and Medium Scenarios has very similar spatial pattern to the 2025 High Scenario, and show similar reduction compared to the 2011 Base Year.

Figure 5-25 shows contribution from total new Federal O&G in Colorado to W126 Cumulative Ozone Exposure Index (Source Group X) in the 2025 High, Low and Medium Development Scenarios. The contribution of new Federal O&G in Colorado is very small for all three scenarios with spatial maximums of 0.82, 0.24, and 0.71 ppb, respectively. The maximum contribution from Source Group X to W126 within the 12/4 km domain occurs in the White River FO for the High and Medium Scenarios, and occurs in the CRVFO for the Low Scenario.

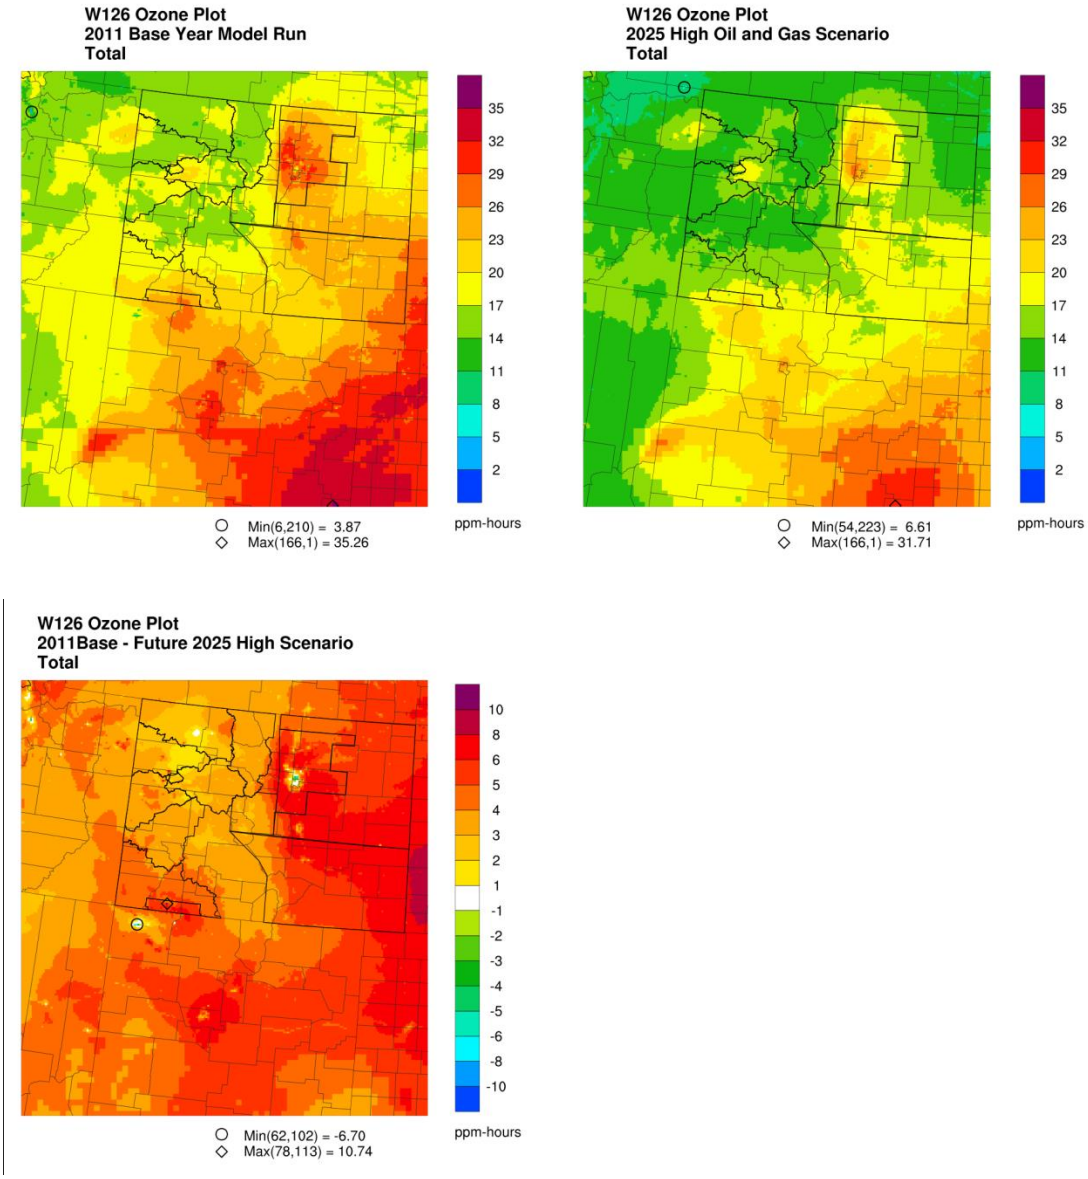

Figure 5-24. W126 Cumulative Ozone Exposure Index for 2011 Base Year (upper left), 2025 High Development Scenario (upper right), and their difference (lower left).

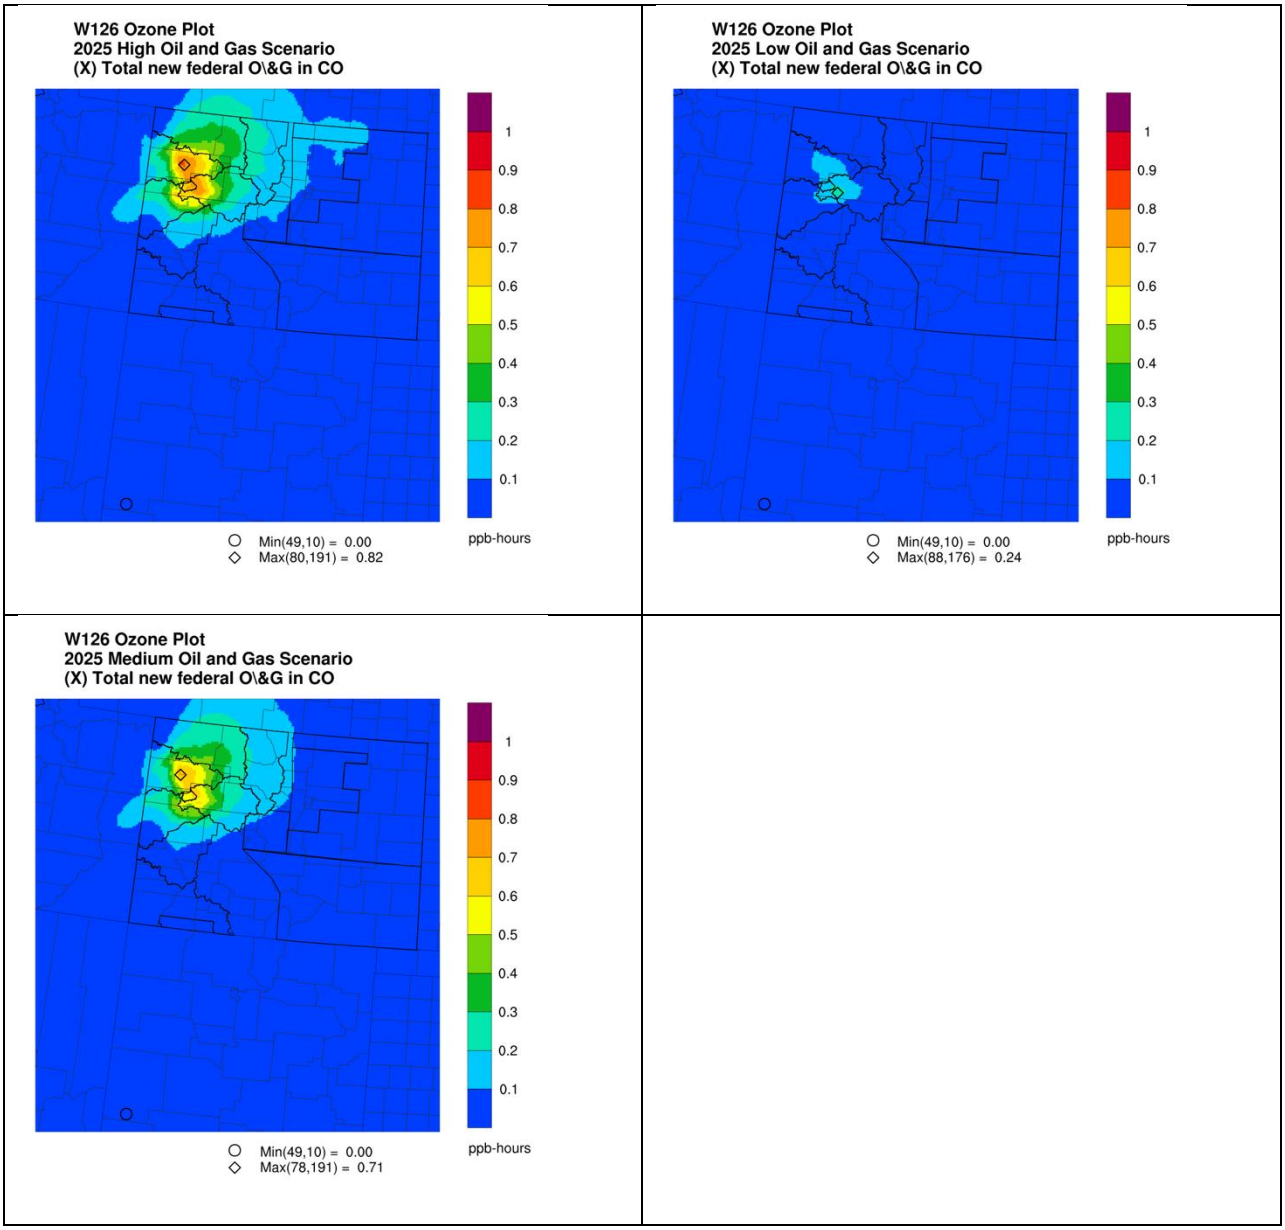

Figure 5-25. Contribution from total new Federal O&G in Colorado to W126 Cumulative Ozone Exposure Index (Source Group X) in the 2025 High, Low and Medium Development Scenarios.
