RE: Leasing 258.9 acres at Lewisville Lake, TX parcel

Dear BLM,

We are writing to strongly protest the inclusion of the Lewisville Lake, Texas parcel in the listings for the Competitive Oil and Gas Lease Sale on April 20, 2016. The Lewisville Lake parcel should not be leased for gas exploration, drilling, or production. We are local residents *extremely concerned* about contamination of our drinking water, which comes from Lewisville Lake. Drilling operations and the hydraulic fracturing process that is used to extract natural gas from the Barnett Shale underlying Lewisville Lake pose serious risks to the lake's many ecosystems, the local economies based on use of the lake, and thousands of residents who rely on the lake for their water supply. Here, we reference scientific research to support our fears about habitat destruction and surface water contamination from hydraulic fracturing. If this occurs at Lewisville Lake, it would be an economic, environmental, and health disaster, much like what is occurring in Flint, Michigan today.

There are several recent studies that show surface water contamination through spills of chemicals during transport to and from the fracturing site, the drilling and fracturing processes, improper treatment and disposal of wastewater, failure of well casings, and from structural failure in abandoned wells (Ingraffea et al. 2014; Kell 2011; Mauter et al. 2014; Rozell and Reaven 2012). Unfortunately, full knowledge about the types and magnitude of contamination to date are not possible due to many unknowns about the chemical components in fracturing fluids and limited release of information by drilling companies. For example, although the State of Texas mandates that companies disclose hydraulic fracturing chemicals to FracFocus, companies are still allowed to withhold specific chemicals by labeling them as proprietary. A recent study found that operators in Texas have invoked the exemption to shield the identities of more than 170,000 chemical ingredients since the law took effect in February 2012 (Carroll and Dempsey 2016). This prevents researchers in Texas (including Environmental Impact Assessments conducted by Federal Agencies) from understanding the full health and environmental risks associated with this activity. As well, cumulative measures of contamination are hard because the magnitude of spills and their impact on water quality is

underestimated (Soraghan 2014; Souther et al. 2014). An analysis in Pennsylvania, for example, found that oil and gas operators had not reported 41% of spills (Souther et al. 2014).

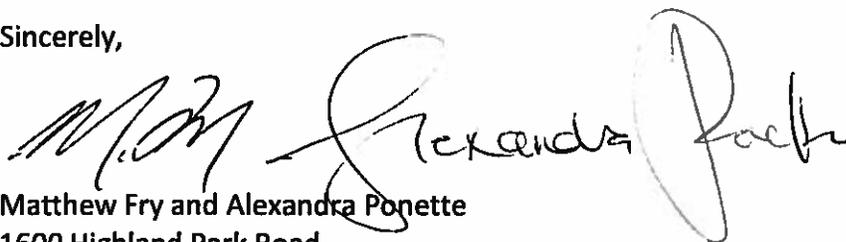

The lack of full disclosure of fracturing chemicals is also disconcerting given recent studies showing possible links between hydraulic fracturing and negative human health effects. For example, Hill (2013) found that exposure to shale gas drilling within a 1.5 mile radius increases the prevalence of low birth weight and McKenzie et al. (2014) found higher incidents of birth defects in areas with dense gas well concentrations. Kassotis et al. (2013) also detected elevated concentrations of endocrine disrupting chemicals in surface water samples collected in dense drilling areas. Thousands of Dallas and Denton County citizens rely on Lewisville Lake as their *only* water source. It is not worth risking even one citizen's health, let alone thousands, for a relatively small amount of natural gas.

There are also clear ecological impacts from hydraulic fracturing and drilling activity. Johnson et al (2015) find evidence that gas well activity likely alters local stream macroinvertebrate community structure due to increased turbidity and chlorophyll a concentrations. Brittingham et al. (2014) show how land clearing for drill sites negatively affects species and habitats, especially forest habitat and forest specialists, sagebrush habitat, vernal pond inhabitants and stream biota. These are precisely the environments at risk in the Lewisville Lake area. Moreover, Thompson et al. (2015) measured bird species responses to hydraulic fracturing wells and demonstrated that the potential ecological effects of an individual gas well are multiplied because of the clearance of roads and the pad site, in addition to the drilling activity.

Every month, more peer-reviewed scientific studies demonstrate the short-term and likely long-term negative ecological and health impacts of surface drilling and hydraulic fracturing. It is imperative that a publicly-funded institution such as the BLM not become party to this high-risk activity, especially given the very serious concerns about contamination at Lewisville Lake. Like the high lead concentrations in the water supply of Flint, Michigan, a similar public disaster will occur if Lewisville Lake is contaminated as a result of the BLM's decision to lease the minerals below the Lake to shale gas operators.

For all of the reasons outlined above, we implore you to remove the Lewisville Lake parcels from the April Lease Sale.

Sincerely,
